Mental Models of the Stock Market

Peter Andre, Philipp Schirmer, Johannes Wohlfart

March 28, 2024

Abstract: Investors' return expectations are pivotal in stock markets, but the reasoning behind these expectations remains a black box for economists. This paper sheds light on economic agents' mental models – their subjective understanding – of the stock market. We conduct surveys with the general population, retail investors, financial professionals, and academic experts. Respondents forecast and explain how future returns respond to stale news about the future earnings streams of companies. We document four main results. First, while academic experts view stale news as irrelevant, households and professionals often believe that stale good news leads to persistently higher expected future returns. Second, while academic experts refer to market efficiency to explain their forecasts, households and many professionals directly equate higher future earnings with higher future returns, neglecting the offsetting effect of endogenous price adjustments. Third, additional experiments with households demonstrate that this neglect of equilibrium pricing does not reflect inattention to trading or price responses but rather a gap in respondents' mental models: they are unfamiliar with the concept of equilibrium. Lastly, we illustrate the consequences of equilibrium neglect. We use panel data on household expectations to show that equilibrium neglect predicts previously documented belief anomalies such as return extrapolation and pro-cyclicality.

1 Introduction

Stock markets revolve around market participants’ return expectations. Return expectations shape investment decisions, their heterogeneity generates trading, and expectation anomalies can drive important market-level phenomena such as excess volatility and bubbles (Adam and Nagel, 2023; Barberis et al., 2015, 2018; Giglio et al., 2021a). Investors’ deeper understanding – their “mental model” – of the stock market will likely play a critical role in the formation of these expectations. However, conventional data on aggregate stock prices, agents’ trading decisions, and even data on subjective expectations remain silent on agents’ reasoning and subjective understanding. Thus, even though return expectations are pivotal in stock markets, the mental models underlying agents’ return expectations are not well understood.

In this paper, we aim to open this black box and empirically explore the mental models that underlie agents’ stock return expectations. We focus on agents’ inference from “stale” fundamental earnings news to expected future returns. This setting allows us to distinguish between three broad classes of mental models. Agents who hold a model of *efficient markets* believe that news about future expected earnings is immediately priced in and will not be informative about future expected returns. Agents whose model features *temporary mispricing* believe that the market equilibrium can temporarily deviate from efficient pricing because of under- or overreaction to news. By contrast, agents who *neglect equilibrium pricing* ignore that stock prices change to offset changes in expected future earnings. They believe that higher expected earnings directly translate into higher expected returns.

To shed light on agents’ mental models, we adopt a tailored survey-based approach that combines rich expectation data with qualitative text data on agents’ reasoning. We field our survey with a diverse group of economic agents: households from the US and the German general population, US and German retail investors, US financial advisors, fund managers employed at large German asset management companies, and international academic experts, who provide a state-of-the-art academic benchmark. In addition, we run a series of experiments with US households to explore the roots of households’ mental models, and we investigate their consequences for belief formation. In total, we interview more than 11,000 households and investors.

Our empirical methodology is comparable across samples and hinges on scenarios that present participants with news relevant to the future earnings stream of a specific company. Participants read two alternative scenarios, one describing a relatively neutral and expected event (e.g., “Nike maintains supplier partnership”), the other describing either good or bad unexpected news (e.g., “Nike secures cost-saving partnership”). Crucially, the news is four weeks old, which means that, depending on their mental models, participants should reason very differently about the “stale” news’ impact on future re-

turns. Participants predict in which of the two scenarios the expected future stock return of the company would be higher. Then, they explain the reasoning underlying their return forecast in a qualitative open-ended question. Lastly, they predict differences in the company's earnings and risk profile across the two scenarios for multiple horizons. We primarily rely on hypothetical news scenarios, which allows us to hold constant the information sets across respondents and simplifies the collection of text data on respondents' reasoning. However, we demonstrate the robustness of our main results to relying on real news items instead.

We document four main results. In a first step, we investigate whether respondents believe that stale news about future earnings still matters for companies' future stock returns. Few academic experts think so, with about 70% predicting no change in future returns in response to stale news. This stands in stark contrast to the forecasts of general population respondents, retail investors, and financial professionals. Across the different scenarios, 50% to 80% of the general population respondents predict higher returns over the next 12 months in response to four-week-old positive news about future earnings (and lower returns for negative news, respectively). This share declines for periods exceeding 12 months, yet remains high at around 40%, even for annual returns four years into the future. Among retail investors and financial advisors, we observe a similar picture as in the general population samples: around 75% of retail investors and financial advisors predict higher (lower) returns in response to stale good (bad) news. Among fund managers, around 51% make such "news-congruent" return forecasts.

In a second step, we explore which mental models of the stock market are underlying respondents' return forecasts. The open-ended question included in our survey asks respondents to explain their prediction. The responses to this question provide a direct lens into participants' reasoning, and the open-ended format ensures that respondents express what is on top of their minds without being primed on any specific mechanism or argument. To preserve the richness of the data, responses are manually classified according to a pre-designed coding scheme. Reasoning in line with market efficiency is dominant in the expert sample. For example, a typical academic expert argues that "[t]he effect on future profits and dividends should already be reflected in the current price." By contrast, respondents from the general population, retail investors, and financial advisors justify their return forecasts by referring to changes in companies' earnings, arguing, for example, in terms of profit margins, sales volume, or production costs. Households and financial advisors thus directly link differences in expected future company earnings with differences in expected future returns, neglecting the equilibrium price adjustments that should have occurred over the previous four weeks. Even among fund managers, 34% express such reasoning, while the rest is mostly split between arguments referring to market efficiency or temporary mispricing due to under-

or overreaction.

We confirm these observations based on two complementary approaches. A belief in market efficiency and risk-based asset pricing would imply that expectations about uncertainty and risk factor exposure account for expected return differences. This is indeed what we observe among academic experts. On the other hand, investors who neglect equilibrium pricing should predict returns to co-move with the future earnings that can be expected for the company, and this is indeed what we observe among general population respondents, retail investors, and financial advisors. Among fund managers, both predicted risk factor exposure and earnings positively co-move with return forecasts, consistent with a prevalence of both types of mental models. Proxies for beliefs in over- or underreaction of other market participants, included in our households and financial advisors surveys, are only weakly related to return forecasts – at odds with beliefs in many forms of temporary mispricing.

Moreover, we conduct an additional experimental intervention with US households that explicitly asks respondents to envision that risk exposure and uncertainty are the same across the two scenarios or that the news has already been fully priced in. If risk-based reasoning or beliefs in temporary mispricing were underlying households' forecasts, we would expect strong shifts in their return predictions in response to these interventions. Yet, neither intervention significantly reduces the proportion of respondents forecasting higher returns in response to stale news of higher future earnings. Taken together, the data show that while academic experts reason in terms of market efficiency, the mental models of general population respondents, retail investors, financial advisors, and a portion of fund managers link changes in expected earnings to changes in expected returns and neglect equilibrium price adjustments.

In a third step, we conduct two additional experiments with US households to better understand the origins of equilibrium neglect. The neglect could result from inattention to the trading responses by market participants and the ensuing changes in stock prices, in line with the behavioral phenomenon that indirect, contingent, and downstream consequences typically receive less attention (Bordalo et al., 2022b; Eyster, 2019; Gabaix, 2019; Niederle and Vespa, 2023). Therefore, the first experiment draws participants' attention to potential trading reactions and the ensuing price changes over the four weeks since the news announcement. Yet, even though households report that investors traded in response to the news and that stock prices changed accordingly, these interventions do not affect the proportion of respondents who infer higher returns from stale good news. The neglect of equilibrium pricing thus seems to result from a deeper "gap" in respondents' mental models: they simply do not understand that the price adjustment triggered by the news will (eventually) offset the change in expected future earnings. To experimentally test this idea, an additional intervention explains to respondents the

Table 1 Overview of the results

Result	Method
<p>(1) Inference from stale news (Section 3) Academic experts think that stale earnings-relevant news do not predict future stock returns. Many other investors believe they do.</p>	Seven surveys. Respondents predict stock returns in scenarios with stale news. General population, retail investors, financial advisors, fund managers, and academics.
<p>(2) Mental models (Section 4) Academic experts believe in market efficiency. Non-experts and a share of fund managers neglect equilibrium pricing and directly infer higher expected returns from higher expected earnings.</p>	Three strategies. (a) Qualitative text data. (b) Co-movement of expectations. (c) An additional experiment that rules out risk-based reasoning and temporary mispricing.
<p>(3) Drivers of equilibrium neglect (Section 5) Equilibrium neglect does not result from a lack of attention to past price changes and trading. Rather, households do not understand equilibrium – there is a gap in their mental model.</p>	Two experiments with households. (a) The first draws attention to past trading and price changes. (b) The second explains equilibrium to participants, “fixing” the gap in their model.
<p>(4) Equilibrium neglect and belief anomalies (Section 6) Equilibrium neglect is linked to the extrapolative and procyclical nature of return expectations.</p>	We correlate equilibrium neglect with expectation anomalies in household expectation panel data.

concept of equilibrium and how expected future earnings are incorporated into prices in financial markets. This intervention substantially reduces the fraction predicting higher returns in response to good news by 21 percentage points. The effect persists in a follow-up survey conducted a few days later. Thus, rather than inattention, a fundamental unfamiliarity with equilibrium is central to households’ return predictions.

In a final fourth step, we include our survey module into one wave of the Bundesbank Online Panel Households (BOP-HH) to examine whether equilibrium neglect predicts previously documented “anomalies” in households’ real-world expectation formation. Previous work has established that households’ expectations about aggregate stock returns are positively related to expected and actual overall economic growth (Amromin and Sharpe, 2013; Beutel and Weber, 2022; Giglio et al., 2021a), contrary to standard asset pricing logic. This “pro-cyclicality” could be driven by a mental model that directly links expected earnings to expected returns, neglecting equilibrium price adjustments. Moreover, many economic agents seem to extrapolate past returns (Greenwood and Shleifer, 2014; Vissing-Jorgensen, 2003). Return extrapolation is quite natural from a mental model that links expected earnings and returns: high past returns often reflect price increases due to good news about future earnings; this good news, in turn, leads agents to expect high future returns. In our data, individuals who exhibit equilibrium neglect are indeed more likely to form pro-cyclical and extrapolative return expectations.

The four results of our paper are summarized in Table 1. Taken together, they high-

light that heterogeneity in return expectations has deep roots and that understanding these roots can help us make sense of previously documented anomalies in expectations and trading behavior. We discuss these implications below.

Implications and related literature Expectations are central in financial markets and have hence attracted a large empirical literature (Adam and Nagel, 2023). These studies have used observational survey data (Adam et al., 2017; Bordalo et al., 2019, 2023b; De La O and Myers, 2021; Giglio et al., 2021a,b) or experiments (Beutel and Weber, 2022; Chinco et al., 2022; Fuster and Zafar, 2023; Haaland et al., 2023; Laudenbach et al., 2024) to understand how expectations are formed and how they affect individual- and market-level outcomes. We contribute to this literature by providing the first direct evidence on economic agents' reasoning – the mental models – behind their return expectations. We show that these models do not necessarily align with prevailing economic theories, making it necessary to empirically study and uncover mental models “in the wild”. In particular, households and many financial professionals struggle to grasp the consequences of equilibrium price adjustments.

This critical gap in their mental model of financial markets helps to understand a series of previously documented anomalies in expectation and trading data. We show that equilibrium neglect is linked to the pro-cyclical and extrapolative nature of return expectations (Amromin and Sharpe, 2013; Beutel and Weber, 2022; Da et al., 2021; Giglio et al., 2021a; Greenwood and Shleifer, 2014; Vissing-Jorgensen, 2003). Equilibrium neglect could also contribute to the tendency to trade on stale news (Tetlock, 2011), phenomena such as over-trading (Barber and Odean, 2000; Odean, 1999), or investors' failure to understand that dividend payout reduces stock prices (Hartzmark and Solomon, 2019). If one believes that expected future earnings indicate higher future returns, successful stock investment requires adjusting the portfolio in response to earnings news and identifying companies that are expected to achieve high earnings. This could explain (i) high perceived stock market participation costs, which discourage stock market participation (Gomes et al., 2021), and (ii) a preference for active investment strategies conditional on participation (Haaland and Næss, 2023). Thus, mental models likely have significant downstream consequences for beliefs and behavior.

The fact that equilibrium neglect is so widespread among retail investors and financial professionals and also occurs among professional fund management teams suggests that equilibrium neglect is also relevant for market-level outcomes. Our results thus strongly support theoretical work that integrates non-standard belief formation mechanisms into macro-finance models and illustrates their asset pricing consequences (Adam and Nagel, 2023). For example, the extrapolation of returns that equilibrium neglect could produce can lead to momentum and price reversals (Barberis et al., 2015; Cut-

ler et al., 1991; De Long et al., 1990; Jin and Sui, 2022), while disagreement about the correct model can generate high trading volume (Barberis et al., 2018; Hong and Stein, 2007). Other studies explore the consequences of imperfect inference from equilibrium prices (Adam et al., 2017; Bastianello and Fontanier, 2023, 2024; Eyster et al., 2019; Hong and Stein, 1999; Schmidt-Engelbertz and Vasudevan, 2024). For example, Bastianello and Fontanier (2023, 2024) study learning from prices when market participants neglect that others do so as well. This “partial equilibrium thinking” generates overreaction, excess volatility, high trading volume, and return predictability. Imperfect inference from equilibrium prices appears highly plausible in light of our results. Moreover, since our paper primarily focuses on inferences from stale, fundamental earnings news to future returns, it suggests a new mechanism that theory has yet to explore. One intriguing implication of this mechanism is that it links earnings expectations to return expectations and can thus also link the extrapolation of fundamentals (Barberis et al., 1998; Bordalo et al., 2022a, 2023b; Hirshleifer et al., 2015) to return extrapolation.

We also contribute to recent work on the foundations of attention and model misspecification (Bordalo et al., 2023a, 2022b; Enke, 2020; Esponda et al., 2023; Gabaix, 2019; Gagnon-Bartsch et al., 2023; Graeber, 2023; Hanna et al., 2014; Schwartzstein, 2014; Schwartzstein and Sunderam, 2021). Individuals often struggle to comprehend indirect and contingent consequences (Dal Bó et al., 2018; Eyster, 2019; Greenwood and Hanson, 2015; Niederle and Vespa, 2023), here: the market’s pricing response. Our mechanism experiments show that if the model is misspecified and does not attribute an important role to the market response, increasing attention to this response is futile. Instead, an effective intervention needs to address the gap in individuals’ mental models. Our evidence thus highlights the complementary nature of attention and mental models and emphasizes the importance of studying mental representations of the world. Indeed, a growing empirical literature explores lay economic thinking in various contexts, such as macroeconomic shocks and policies (Andre et al., 2022a,b; Coibion et al., 2023, 2022, 2018), taxation (Stantcheva, 2021), and trade (Stantcheva, 2023). Hirshleifer (2020) argues that understanding mental models in financial market contexts is a critical research goal in finance. In our study, we aim to open this black box and empirically explore investors’ mental models of the stock market.

2 Empirical strategy: Measuring mental models

2.1 Three mental model types

Our goal is to understand which mental models shape agents’ stock return expectations. In general, we use the term “mental model” to denote beliefs about how different vari-

ables are connected – for example, expected future returns and expected future earnings – together with the reasoning about the mechanisms underlying these relationships. We focus on inference from stale fundamental earnings news to future returns, as different mental models suggest very different interpretations of such news.

To fix ideas, contrast two scenarios in a simple thought experiment. News about a large exchange-traded company broke four weeks ago. In the first scenario, the news was neutral; in the second scenario, it was good news about the company's future expected earnings and, hence, the future dividend stream of its stock. How could agents' return expectations for an investment in the stock today – four weeks after the news broke – differ between the two scenarios? We distinguish between three broad classes of mental models.

Efficient markets and risk-based asset pricing According to this view, equilibrium asset prices fully reflect all publicly available information at any point in time (Fama, 1970). News about future expected earnings is immediately priced in since arbitrage opportunities cannot exist in equilibrium. As a result, agents who believe in market efficiency believe that past public news about expected future earnings is completely irrelevant for future expected returns. Instead, the expected return arises as compensation for the risk properties of the stock – the risk premium – plus the risk-free rate. As long as the stock's risk properties do not differ, the expected future return is identical across the two scenarios.

Temporary mispricing Agents who follow a model of temporary mispricing believe that the market equilibrium can temporarily deviate from efficient pricing. The reasons can be manifold. For example, if traders are inattentive and arbitrage is limited, the market underreacts to news, prices move only slowly to the efficient price as the news spreads, and expected returns are temporarily higher in the good news scenario (Jegadeesh and Titman, 1993). By contrast, if traders become initially too optimistic after hearing the good news, the market overreacts to the news, prices overshoot, and later reverse towards the efficient price (De Bondt and Thaler, 1985). Expected returns can be higher or lower depending on the timing of market entry and the return reversal. There are many specific models for why temporary mispricing can occur in equilibrium after earnings news arrives, but they all share the idea that, in addition to the risk-free rate and the risk premium, under- or overreaction shape expected returns.

Equilibrium neglect Both of the above models feature equilibrium price adjustments, which break any direct link between the future expected earnings of a company and the future expected returns of an investment in this company. By contrast, we say that an agent's model neglects equilibrium pricing if they directly infer higher expected returns from higher expected earnings. The question “Which stock investments can be expected to succeed?” is perceived as interchangeable with the question “Which company can

be expected to succeed?” Agents neglecting equilibrium pricing would predict higher future returns in the scenario with higher expected earnings. As we will see, this does not necessarily mean that agents do not understand that prices respond to news, but they do not consider what this price response implies for future returns.

This broad classification of mental models is not exhaustive, but it captures the two prominent classes of equilibrium models and a third, as we will find, quite common form of non-equilibrium thinking. These models have very different implications for how return expectations are formed, which motivates us to study their empirical prevalence.

2.2 Survey design

Because the three model types interpret stale news so differently, expectation formation in response to stale news is an ideal environment to investigate agents’ mental models. Our empirical strategy relies on this insight, translates the above “thought experiment” into concrete terms, and implements it in tailored surveys with a diverse set of economic agents.

Scenarios In the survey, each respondent is asked to think about a pair of hypothetical scenarios: a scenario with neutral stale news and a scenario describing either positive or negative stale public news for the future earnings stream of a company.¹ We describe the news as four weeks old.² We repeat this information multiple times, including in all subsequent prediction questions, and even ask for it in a comprehension quiz to ensure that the information is salient. We also highlight that the news is public and received attention. Our main scenarios describe news about Nike, the multinational athletic footwear and apparel corporation. In the condition with neutral versus good news, the scenarios read as follows:

Scenario 1: Nike maintains supplier partnership

Four weeks ago, on [. . .], Nike Inc. announced the continuation of its partnership with major polyester supplier Toray Industries Inc., in a move aimed at retaining its current supply chain. The continuation of the partnership is expected to maintain the company’s current cost structure. Industry experts were not surprised by the announcement, as continuity in supplier relationships is a common practice in the industry.

¹Of course, we cannot guarantee that the neutral news is perceived as perfectly uninformative, but our approach only requires that good news is perceived as relatively better news (and bad news as relatively worse news).

²The news is described as four weeks old because we want to abstract from very short-run mispricing (e.g., Medhat and Schmeling, 2022). In theory, efficient markets respond immediately, but we do not want to take a stance on what counts as “immediate” in the real world. Hence, we adopt a conservative approach: if respondents think the public news is still not fully reflected in prices four weeks later, they certainly do not believe in market efficiency.

Scenario 2: Nike secures cost-saving partnership

Four weeks ago, on [. . .], Nike Inc. announced a new strategic partnership with leading recycled polyester supplier Unifi Inc., aimed at reducing raw material costs by 20%. The deal is expected to have a significant impact on Nike's bottom line, making its products more price-competitive. Industry experts were pleasantly surprised by the news and dubbed it an "unexpected success" for the company. They projected the move to significantly enhance Nike's market position in the sports apparel industry.

In both scenarios, the announcement was made four weeks ago and received a lot of attention from stock market traders.

An analogous survey condition contrasts neutral with *bad* news. There, Nike announced a significant disruption of its supply chain. Industry experts were negatively surprised by the news and projected that this significantly weakens Nike's market position. Respondents are randomized into one condition.

We deliberately use a real-world company and realistic business news and present them in a journalistic style to render the situation concrete, tangible, and naturalistic. Not every group of our respondents might be equally able to access or articulate an abstract mental representation of the stock market, but their underlying views and understanding will become visible in concrete examples. Moreover, focusing on an individual stock rather than the aggregate market allows us to abstract from changes in the risk-free rate or risk aversion.

The hypothetical nature of the scenarios has three key advantages. First, it gives us full control over all the details of the news events. Second, it allows us to ensure comparable information sets across participants, which is crucial given the diverse background knowledge of our heterogeneous respondent groups. Third, it allows us to present each respondent with both a neutral and an alternative positive/negative news scenario, which implies that we can directly elicit our object of interest: the perceived *difference* in expected returns across the two scenarios. This approach controls for heterogeneity in the level of return expectations across individuals and samples and facilitates the open-ended elicitation of how people reason about the *effect* of stale news on future returns.

However, this approach also has potential drawbacks: respondents' reasoning could be specific to the details of the scenarios, they could find hypothetical news less credible, we cannot incentivize forecasts, and presenting each respondent with two scenarios could make respondents overly sensitive to the differences between the scenarios. These issues could be particularly relevant for respondents from the general population, who are the least familiar with the general principles governing stock markets. To address these concerns, we replicate the results in eight additional conditions with alternative scenarios in our surveys with the general population. Moreover, we demonstrate the

robustness of our main result in an additional between-subject study with households that relies on real news items and incentivized return forecasts (discussed in Section 3).

Measuring expectations and reasoning After respondents have read the scenarios and passed a comprehension quiz, they are asked to envision that they invest \$1,000 into the company’s stock on the survey day, four weeks after the news was released. They are asked to predict whether the expected return will be higher in the first scenario, similar in both scenarios, or higher in the second scenario.³ We focus on directional predictions (higher/similar/lower) to ensure that the question remains meaningful and answerable for groups with lower levels of financial knowledge. On the subsequent page, respondents explain their return prediction in their own words. Later, they also forecast (directional) differences in earnings, the uncertainty of the return, and the exposure to systematic risk factors for each of the next five years. In our longer surveys, we also measure directional expectations for investments made one, two, three, or four years in the future, and we elicit quantitative first- and second-order return expectations for the next twelve months. Appendix D.1 presents the instructions for our key survey questions. The complete instructions, including additional questions on respondents’ economic background and financial literacy, are available online at <https://osf.io/b83gf>.

The approach allows us to investigate respondents’ mental models through three complementary strategies. First, the expectation data allow us to document respondents’ inference from stale news to future returns. Moreover, we can explore which models are consistent with the co-movement of respondents’ return, earnings, and risk predictions. Second, the explanation data provide a direct lens into respondents’ reasoning. Third, we can integrate our module into additional experiments that shed further light on people’s understanding.

2.3 Samples

The final requirement for our empirical strategy is access to data from different types of economic agents. We therefore launch multiple surveys. Appendix Table B.1 provides an overview of all our data collections.

General population (US, $n=2,434$) We conduct our US general population survey in June and July 2023 in collaboration with the survey company Dynata. Our sample of 2,434 households closely aligns with the general US population in terms of gender, age, region, and income (Appendix Table B.2). As is common in online surveys, our sample

³Respondents are told that “similar” indicates a return difference of at most 0.5 percentage points. At the start of the survey, all respondents receive a non-technical definition of stock returns to ensure a common understanding. We clarify that the return of a stock comprises both price changes – i.e., capital gains/losses – and dividend payments.

overrepresents college-educated individuals (sample: 47%, population: 33%). 58% of our respondents report owning stocks.

General population (Germany, $n=3,852$) We include a condensed version of our survey in the June 2023 wave of the Bundesbank Online Panel (BOP-HH), an established panel survey on household expectations. 3,852 households with diverse background characteristics complete our module (Appendix Table B.2). Due to restrictions from the Bundesbank, we rely on fictitious company names but hold all other aspects of the scenarios constant. The German sample allows us to replicate our results in a different cultural context and to relate respondents' mental models to their real-world expectations.

Retail investors (US, $n=408$) To survey households who invest a substantial share of their wealth in stocks, we recruit 408 US retail investors via the survey platform Prolific in August 2023. 81% of the investors have a college degree, and 91% report an income of \$100,000 or more. The median respondent holds financial assets worth \$225,000, has 47% of her financial wealth invested in stocks or stock mutual funds, and conducts two equity trades per quarter (Appendix Table B.2).

Retail investors (Germany, $n=299$) In November and December 2023, we also recruit 299 retail investors who hold a portfolio at a large German online bank. The sample has a relatively high fraction of male respondents (88%), and the average age is 49 years. Respondents report a median financial wealth of 137,500 EUR, with 51% invested in equity, and conduct two equity trades per quarter. For comparability, we use the same fictitious company names as in the German general population survey.⁴

Financial advisors (US, $n=406$) In June 2023, we also survey a sample of 406 financial professionals who advise or trade for households. We collaborate with CloudResearch, a provider specializing in surveys with hard-to-reach populations, which has been used in prior work on stock investment decisions (Chinco et al., 2022). Summary statistics are displayed in Appendix Table B.2. 50% of the respondents report that providing financial advice is part of their professional activities. They advise a median number of 22 clients and have on average 10 years of experience in providing financial advice. The remaining respondents indicate trading or financial analysis among their key roles. For simplicity, we refer to this sample as our "financial advisors" sample. It reflects the base segments of the financial industry.

Fund managers (Germany, $n=105$) To survey financial professionals trading substantial amounts in the stock market, we collaborate with two large German asset management companies. For both companies, the total assets under management are in the hundreds of billions of euros. The companies agreed to distribute a shortened version

⁴Due to the bank's data protection policies, we cannot link survey responses to administrative data on clients' investment and trading decisions.

of our survey among their fund management teams, which 105 respondents answered in the time between November 2023 and March 2024. We were only able to include a handful of background questions. The fund managers in our sample report an average experience of 16.2 years in their professional role. This sample reflects a population whose decisions have significant market-level implications.

Academic experts (international, $n=116$) In June 2023, we also invite academic economists to participate in a short version of the survey. We invite experts who have published articles with the JEL code “G: Financial Economics” in a set of leading finance journals or the “top five” economics journals between 2015 and 2019. A total of 116 experts participated in our survey. 40% of the experts are based in the United States, and 96% are male (Appendix Table B.3). On average, they completed their PhD 18.6 years before the survey. They have on average 1.7 publications in the “top five” economics journals and 4.2 publications in the “top three” finance journals. Their average Google Scholar h-index is 20.98, and their average citation count amounts to 6,594 (as of August 2023). Thus, our expert sample consists of highly experienced researchers in financial economics with significant academic impact. Their responses provide us with a state-of-the-art academic benchmark for the forecasts elicited in our survey.

As we describe above, the surveys sometimes differ between samples due to logistical constraints. Appendix Table B.1 provides an overview of these differences, but wherever relevant, we highlight them in table or figure notes, footnotes, or the main text.

3 Inference from stale news to future returns

This section describes the first step of our analysis: we investigate how respondents expect stale news about future earnings to affect future returns.

Figure 1 compares the expected differences in returns over the next 12 months between the bad/good news and the neutral scenario across our different samples. We focus on the main version of our survey module featuring news about Nike. Among academic experts, a large majority predict returns to be similar in the good/bad news and the neutral scenarios (67% for the good news and 76% for the bad news arm). Hence, most experts do not think stale news matters for future returns.

This contrasts strongly with the patterns observed in the other samples. Majorities of financial professionals, retail investors, and general population respondents expect returns to be higher in response to four-week-old good news about future earnings and lower in response to four-week-old bad news. The tendency to make such “news-congruent” predictions is most pronounced among retail investors, with 75% and 81% of US retail investors (74% and 75% of German retail investors) making news-congruent

Figure 1 Directional return expectations across samples

Notes: This figure shows the distributions of directional expectations about the difference in the expected stock return over the next 12 months between the *Nike good news* and the neutral scenario (Panel A) and between the *Nike bad news* and the neutral scenario (Panel B) in our samples of academic experts, financial professionals, retail investors, and respondents from the general population. In the surveys with German retail investors, the German general population, and some of the fund managers, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios.

forecasts in the good and bad news arms, respectively. However, the fractions are also large among fund managers (58% and 45%), financial advisors (63% and 75%), US general population respondents (65% and 76%), and German general population respondents (59% and 54%).^{5,6}

The return differences expected by non-experts are quantitatively meaningful and long-lived. We draw on additional expectation data from the longer household and financial advisors surveys to illustrate this. For instance, US retail investors on average anticipate Nike’s stock return to be 3.7pp higher over the next year in response to four-week-old good news and 7.3pp lower in response to bad news (Appendix Figure A.1). A considerable portion of non-experts continue to make news-congruent forecasts for

⁵We also examine how the return forecasts of non-experts vary with their background characteristics (see Appendix Table B.7). Most importantly, a higher level of financial literacy – as measured with the “Big 3” questions commonly used in the literature (Lusardi and Mitchell, 2014) – is associated with a *stronger* tendency to expect future returns to move into the direction of stale earnings news.

⁶We think that the lower fraction of news-congruent forecasts in the German general population sample mainly reflects higher response noise. The BOP-HH survey is a taxing survey with many technical questions, and in our short module we could not include a comprehension quiz. Consistent with this, we see in our US sample that more attentive households – proxied, e.g., by a longer survey duration or no mistakes in the comprehension quiz – make *more* news-congruent forecasts.

Figure 2 Directional return forecasts across scenarios

Notes: This figure shows the distributions of directional forecasts about the difference in the expected stock return over the next 12 months between a good/bad news and a neutral scenario. The six bars on the left focus on firm-level news and company stocks, while the four bars on the right focus on aggregate news and the US stock market. The samples consist of respondents from the US general population.

returns one (56% to 65%), two (44% to 46%), three (30% to 40%), or four years (29% to 40%) into the future (Appendix Figure A.2).

Moreover, Figure 2 shows that this tendency extends to various other scenario conditions that we included in the US general population survey to explore the robustness of our results. Most respondents infer higher future returns from past good news (or lower returns from past bad news) in scenarios that feature a successful expansion of Amazon in Africa, Amazon’s surprising withdrawal from South America, Novartis’ harmful loss of a patent suit, or a break-through in the development of a new cancer drug by the German pharmaceutical company Biontech.⁷ Households’ tendency to equate higher company earnings with higher stock returns carries over to the *aggregate* stock market. In four scenarios featuring macroeconomic news, majorities of respondents expect returns of the US stock market to be lower following four-week-old bad news, namely the announcement of an oil price or interest rate increase. Conversely, they expect the stock market to yield predictably higher returns following stale good news, namely a government spending program or a break-through in solar technology.

Finally, we confirm our results in an additional robustness study that relies on real news, a between-subject design, and incentives (Prolific, $n=484$ US households, September 2023).⁸ We use real news about the German company Siemens Energy. Half

⁷We find similar patterns in the corresponding scenarios in the German general population survey, which use fictitious company names. These results are omitted for brevity but are available upon request.

⁸Summary statistics are shown in Appendix Table B.4. Our sample is balanced across the two included treatment arms (see Appendix Table B.5). The survey instructions can be found in Appendix D.2.

of the respondents are randomly assigned to the good news condition and learn that Siemens Energy announced a \$7bn wind power deal four months ago. The other half of the respondents are assigned to the bad news condition and instead learn that, two months ago, Siemens Energy retracted its profit forecast for the ongoing year due to complications in its wind turbine business. Subsequently, all respondents make an incentivized quantitative forecast about the return of the Siemens Energy stock over the next 12 months. Then, they are asked to divide an investment of £100 into Siemens Energy stock and a savings bond that pays a fixed interest rate of 2%, knowing that ten respondents will be selected randomly to be paid according to their choices 12 months later.⁹ Respondents assigned to the good news condition predict a 6.4pp higher return of the Siemens Energy stock over the next 12 months ($p < 0.001$), and they invest a 26.7pp higher share into the Siemens Energy stock ($p < 0.001$, Appendix Table B.8) than those in the bad news condition. These findings show (i) that our main result replicates in a between-subject design featuring real news and incentives and (ii) that households act on their return forecasts by allocating significantly more money to a company's stock depending on which piece of stale news they have been exposed to.

Taken together, our first main result is the following:

Result 1. *Most households, retail investors, and financial professionals consider stale positive or negative news regarding future company earnings to be predictive of correspondingly higher or lower future stock returns. This perception is prevalent across various future horizons and company-specific and aggregate scenarios. By contrast, the overwhelming majority of academic experts do not consider such news to be predictive of future returns.*

The strong differences between the return expectations of academic experts and other investors suggest that they reason very differently about how returns arise in markets. While experts' predictions are consistent with the view that stock markets are mostly efficient, households and professionals could believe in (large) temporary mispricing or neglect equilibrium pricing altogether and directly equate earnings with returns. We distinguish between these different lines of reasoning in the next section.

4 Mental models underlying return forecasts

To explore the mental models underlying respondents' return forecasts, we follow three different approaches. We analyze direct measures of reasoning, the co-movement of expectations about different variables, and experimental interventions. We focus on three broad classes of mental models: (i) market efficiency and standard risk-based pricing, (ii) temporary mispricing, and (iii) equilibrium neglect.

⁹The UK-based survey company Prolific pays US respondents in Pounds.

4.1 Respondents' reasoning

Our first approach exploits our direct measure of the reasoning behind respondents' return expectations. After respondents have made their forecast about the difference in stock returns between the two scenarios, they explain why they made their prediction in an open-text field. Compared to more structured question formats, open-ended questions offer a lens into respondents' reasoning without priming them on any potential line of thought. They do not restrict responses to pre-defined options and allow participants to express their thoughts freely and unconstrained by the researcher (Andre et al., 2022b; Ferrario and Stantcheva, 2022).

Even a quick glance at the qualitative data reveals that academic experts, on the one hand, and respondents from the general population, retail investors, and financial advisors, on the other hand, reason very differently about the effect of stale news. Experts tend to invoke the idea of *market efficiency*, as illustrated by the following response:

“The effect on future profits and dividends should already be reflected in the current price.”

Many experts additionally explain that differences in exposure to systematic risks should be the only source of differences in expected returns:

“In efficient markets, the information should be fully incorporated into the stock price four weeks after the announcement. Thus, going forward Nike will earn its expected return which is the same in both scenarios (as beta did not change due to the announcement).”

By contrast, respondents from the general population tend to invoke differences in company earnings to justify their return forecasts. They directly link stale changes in expected earnings to changes in expected returns, *neglecting the offsetting effect of equilibrium price adjustments*:

“[...] In scenario 2, a disruption in their supply chain would lead to difficulty in maintaining production and therefore income and therefore profits.”

The following general population respondent even refers to stock price changes since the announcement but still expects higher future dividends to lead to higher returns:

“Because although the market had already increased the stock price on the announcement the profit margins would be higher and thus dividends.”

Retail investors and financial advisors tend to follow similar lines of reasoning as households in the general population sample, as exemplified by the following responses:

“Because Nike will continue a positive relationship with its partner and therefore the company can continue to grow profits, increasing the value of the stock.”

“Cost savings of 20% will increase the bottom line of Nike, and therefore increase EPS for the company. I expect my \$1000 investment to also increase as a result.”

As we will see, fund managers’ responses are very heterogeneous, but a neglect of equilibrium pricing occurs even in this sample:

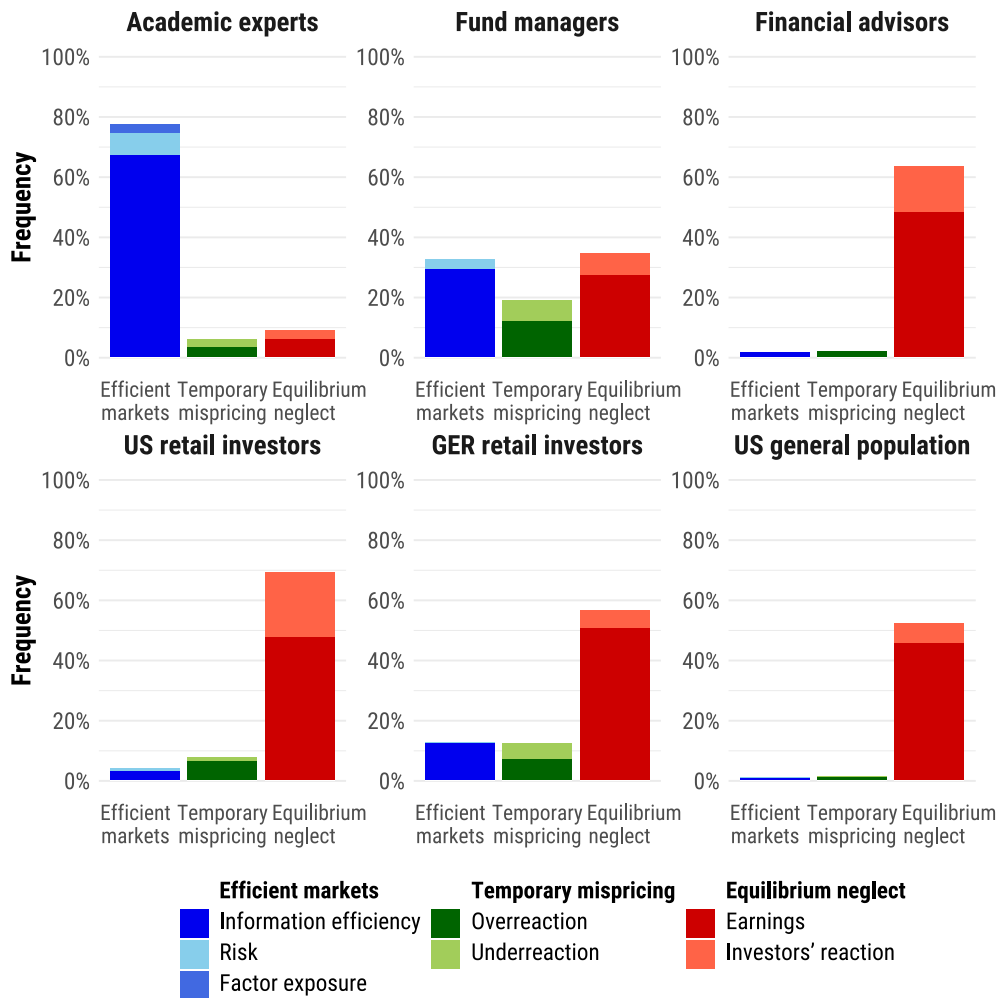

“Based on the – so far – available information I would expect that lower production cost should lead to higher earnings on company side and as such increase total return of the investment.”

The contrast between references to market efficiency among academic experts and the neglect of equilibrium pricing among many non-experts also becomes apparent in a simple quantitative text analysis. The word clouds in Appendix Figure A.3 display the most commonly used words for each sample. Academic experts often use words such as “price”, “information”, “already”, or “incorporated”. Households and financial advisors talk more often about “costs”, “profit”, “supply chain”, or “product”; that is, they talk about the expected future earnings stream to justify their prediction for future expected returns. Among fund managers, both sets of terms appear frequently.

We devise a coding scheme to systematically compare the fractions of responses expressing arguments in line with specific mental models. Trained human coders assign each response to a unique code depending on which line of reasoning the respondent expresses.¹⁰ Our codes encompass references to (i) market efficiency, (ii) changes in uncertainty, (iii) changes in risk factor exposure, (iv) temporary overreaction of stock prices, (v) temporary underreaction, (vi) changes in expected earnings, and (vii) a change in traders’ sentiment, excitement, or outlook for the company. Responses that cannot clearly be assigned to one category are assigned to a residual category. Codes (i)–(iii) describe arguments in line with the notion of efficient markets and standard risk-based asset pricing. Codes (iv) and (v) capture arguments related to temporary mispricing. Codes (vi) and (vii) capture forms of equilibrium neglect, where higher expected earnings or the improved outlook among traders are equated with higher expected returns, neglecting the offsetting effect of price adjustments. The coding scheme and procedure are explained in more detail in Appendix C.2.

¹⁰The coding scheme was devised before the main data collection and informed by both pilot surveys with households and leading asset pricing theories. We work with human coding because we expect that trained humans can more reliably detect the sometimes subtle economic logic in respondents’ explanations than general large language models. An important drawback of human coding is its subjectivity. To address this concern, each coder has economics training and participates in a series of joint training sessions in which we introduce the coding scheme and discuss various examples. Moreover, each response is double-coded by two independent reviewers. Whenever a conflict occurs, the case is revisited by a third coder, and a final decision is made. We observe a high inter-rater reliability: when one reviewer assigns a specific code, there is a 73% chance that the other coder does so as well.

Figure 3 Reasoning underlying return forecasts across samples

Notes: This figure displays the distributions of reasoning underlying respondents' return forecasts as expressed in the open-ended question and categorized using our coding scheme. We pool across the *Nike good news* and the *Nike bad news* survey arms. The underlying samples are academic experts, fund managers, financial advisors, US and German retail investors, and the US general population sample. In the survey with German retail investors and for part of the fund managers, the scenarios use the fictitious company name "SportsApparel" but are otherwise identical to the "Nike" scenarios. The German general population survey does not include an open-ended question on reasoning due to space constraints.

Figure 3 displays the distribution of open-ended responses in our main Nike scenarios, categorized with our coding scheme. We can categorize 93% of the responses from the academic expert sample using our coding scheme, compared to 87% among fund managers, 68% among financial advisors and 69% among households. The smaller fractions in the non-expert samples reflect that non-expert responses are often less precise and harder to classify. We instructed the coders to be conservative and to err on the side of avoiding misclassification.

Among academic experts, 77% argue in line with efficient markets and standard risk-based asset pricing. Merely 6% attribute their return forecast to temporary over- or underreaction of stock prices. Only 9% are classified as neglecting equilibrium pricing by directly linking their return forecasts to changes in future corporate earnings.

In stark contrast, 52% of households in the US general population sample neglect equilibrium pricing and explain their return forecast with changes in expected earnings or investors' excitement about the company outlook. Arguments in line with market efficiency or temporary mispricing are almost absent in this sample. The fact that respondents do not mention changes in risk factor exposure when making return forecasts is striking, given the central role of risk factors in contemporary asset pricing models.¹¹ We find the same dominance of equilibrium neglect among US and German retail investors (69% and 56%, respectively) and among financial advisors (64%), while arguments referring to market efficiency or temporary mispricing are almost absent. Within these samples, more financially literate respondents tend to be – if anything – more likely to express arguments reflecting equilibrium neglect (Appendix Table B.9). This suggests that thinking about equilibrium reflects a facet of financial knowledge that is not captured by the financial literacy measures typically employed in the literature (Lusardi and Mitchell, 2014).

The patterns in the fund manager sample are quite diverse. About 33% of respondents invoke market efficiency, while arguments referring to temporary mispricing are also common at 19%. Strikingly, even in this sample of experienced professional traders, who make high-stakes investment decisions on a daily basis, 35% express reasoning that neglects equilibrium pricing and directly link differences in expected earnings to differences in expected returns.

In additional analyses, we confirm that arguments neglecting equilibrium pricing are prevalent among households for all additional firm-specific scenarios and the aggregate stock market scenarios, where most respondents refer to expected future economic growth and company earnings (Appendix Figure A.4). Moreover, we leverage an additional structured question that presents respondents with a set of pre-formulated statements, largely corresponding to the codes used to categorize the open-ended responses. Again, we find that academic experts are much more likely to select arguments in line with efficient markets, while households and financial advisors display a much stronger tendency to cite changes in corporate earnings as a driver of expected returns (Appendix Table B.12).¹²

Finally, we also investigate the correlation between respondents' reasoning and their return forecasts. We regress a dummy variable indicating whether the respondent

¹¹This finding aligns with recent evidence that many investors do not consider the correlation of stock returns with consumption growth in their investment decisions (Chinco et al., 2022). Our evidence suggests that – in addition to neglecting systematic risk exposure in their own investment decisions – households do not view asset prices and expected returns as primarily reflecting exposure to such risks.

¹²We place this question at the very end of the survey to avoid influencing respondents' forecasts about returns over future horizons, earnings, uncertainty, and risk-factor exposure, which are elicited after the open-ended question. However, this means that respondents have to recall the reasoning behind a forecast made several minutes earlier and that their response to the structured question is likely influenced by the various forecasts they provided in between. Nevertheless, we replicate our main finding.

makes a news-congruent return prediction for the next 12 months (higher returns for stale good news, lower returns for stale bad news) on dummies indicating whether the respondent expresses reasoning consistent with market efficiency and standard risk-based asset pricing or reasoning consistent with a neglect of equilibrium price adjustments. We omit the codes indicating temporary mispricing, as such reasoning rarely occurs in most of our samples. The omitted base category otherwise mostly includes responses that were not assigned to any category. Across all our samples, respondents whose explanation shows a neglect of equilibrium price adjustments are significantly (between 31pp and 60pp) more likely to make news-congruent forecasts (Appendix Table B.10). Conversely, respondents whose reasoning aligns with efficient markets or risk-factor-based asset pricing are significantly (between 34pp and 60pp) less likely to make such forecasts. The differences in reasoning can almost entirely account for the differences in the return forecasts between academic experts and our other samples: these differences are strongly reduced in size and statistical significance once we control for reasoning. The difference only remains significant for retail investors, but even here it drops to only about 15% of its original size (Appendix Table B.11).

4.2 The co-movement of expectations

Our second approach to studying respondents' mental models explores which models are "revealed" by the co-movement of respondents' expectations about different variables. While this strategy is purely correlational, it does not require that respondents are able to articulate their reasoning. It thus provides a complementary approach to assessing the potential of different mental models to account for respondents' forecasts.

In our survey, respondents not only forecast future returns, but they also predict in which scenario market participants expect (i) future earnings, (ii) the uncertainty of the stock return, and (iii) the stock's "exposure to circumstances that investors deem unfavorable" – i.e., to systematic risks – to be higher. Respondents subscribing to the notion of market efficiency and risk-based asset pricing should predict returns to co-move with uncertainty and risk-factor exposure. Respondents neglecting endogenous price adjustments should predict returns to co-move with the future earnings that can be expected for the company.¹³

For US households and financial advisors, we can also draw on quantitative twelve-month first- and second-order return beliefs in the two scenarios to shed light on beliefs in mispricing (Appendix Figure A.1). Specifically, respondents could be overconfident

¹³We deliberately do not elicit individuals' own earnings expectations but their beliefs about the earnings expectations of *market participants*. A co-movement of subjective return expectations and individuals' own earnings expectations could also reflect a belief in mispricing when respondents disagree with the market's earnings expectations. However, a co-movement of subjective return expectations and perceived earnings expectations of market participants is indicative of equilibrium neglect.

in their own belief about what a specific piece of public news implies for a company's future earnings – a key source of disagreement in return expectations in an influential class of asset pricing models (e.g., Scheinkman and Xiong, 2003). For instance, they might expect other market participants to be overly optimistic about the increase in future company earnings implied by positive earnings news. In the eyes of such a respondent, market participants' buying behavior would have driven the stock price to an over-valued level. If the respondent attaches some probability to a market correction, they would decrease their first-order expectation about the future return relative to their second-order expectation when going from the neutral to the good news scenario. The reverse logic applies to respondents who believe that other market participants are too pessimistic about the increase in future company earnings implied by the news. Thus, relative differences in second- versus first-order return expectations across scenarios are proxies for beliefs in particular forms of mispricing.

We study the co-movement of expectations by regressing an indicator for news-congruent forecasts (higher returns for stale good news, lower returns for stale bad news) on dummy variables indicating whether a respondent predicts market expectations about earnings, uncertainty of the return, or exposure to systematic risk to be higher (lower) in response to stale good news (bad news). We also include dummy variables indicating beliefs in overreaction or underreaction of other market participants constructed from the quantitative first- and second-order return expectations.

Table 2, Column 1, presents the results for academic experts. Among them, the perceived earnings expectations of the market are not significantly related to return forecasts. Instead, experts' return forecasts are significantly positively correlated with expected uncertainty ($p = 0.017$) and even more strongly with expected exposure to systematic risk ($p = 0.010$).

By contrast, among financial advisors and households, the perceived earnings expectations of the market seem to be the most central variable in return forecasts (Columns 3–7). For instance, when a US retail investor thinks the market expects company earnings to be higher, the likelihood that the respondent also predicts the return to be higher increases by 39 percentage points ($p < 0.001$). While the expected uncertainty of the return is also correlated with return expectations in the conventional direction (sometimes significantly so), its role is quantitatively much smaller than the role of expected earnings. The coefficient estimates for risk factor exposure are small and, in two out of the five cases, negative – contrary to standard asset pricing logic. Respondents believing in overreaction among other market participants are less likely to predict higher returns in response to good news. Conversely, those believing in underreaction of others are more likely to do so. These patterns are consistent with the future market corrections that would be implied by such over- or underreaction. However,

Table 2 Correlations between directional return expectations and other expectations

R ²	0.196	0.123	0.280	0.194	0.033	0.211	0.283

Notes: This table regresses respondents' directional return forecasts on their forecasts about other variables, pooling across the *Nike good news* and the *Nike bad news* survey arms. The outcome is a dummy variable for expecting the stock return over the next 12 months to be higher (lower) in the good news (bad news) scenario. The independent variables are dummy variables indicating whether a respondent believes that market participants expect earnings, the uncertainty of the return, or the exposure of the return to systematic risk to be higher (lower) in the good news (bad news) scenario. Where available, we also include dummy variables indicating whether the respondent increases (for bad news: decreases) the quantitative second-order return expectation more strongly (by more than 0.5pp) than the quantitative first-order expectation in response to the news ("Others overreacting") and whether the respondent increases (for bad news: decreases) the quantitative first-order return expectation more strongly (by more than 0.5pp) than the quantitative second-order expectation ("Others underreacting"). The underlying samples are academic experts (Column 1), fund managers (Column 2), financial advisors (Column 3), US and German retail investors (Columns 4 and 5), and the US and German general population samples (Columns 6 and 7). In the surveys with German retail investors and with the German general population and for part of the fund managers, the scenarios use the fictitious company name "SportsApparel" but are otherwise identical to the "Nike" scenarios. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

these effects are much smaller and less precisely estimated than the effects of expected earnings.¹⁴

Among fund managers, both earnings expectations and expected risk factor exposure

¹⁴Appendix Table B.13 shows that the patterns for US households and financial advisors are robust to focusing on good and bad news separately and to extending the analysis to all five-year horizons, with or without the inclusion of respondent fixed effects. The latter also suggests that the increasing share of neutral return predictions for later horizons (Figure A.2) is not due to a belief in delayed market efficiency but instead simply reflects respondents' belief that the news' relevance for future earnings fades over time. These patterns are similar for German retail investors, which are omitted to preserve space. The table also highlights that the return forecasts general population respondents provide in the macroeconomic scenarios are strongly positively correlated with their forecasts about aggregate firm earnings and only weakly related to forecasts about other variables.

are positively related to return forecasts ($p = 0.005$ and $p = 0.057$, respectively, Column 2), consistent with a prevalence of both types of mental models in this sample.

Taken together, the results confirm the conclusions from the qualitative text data: households' and financial advisors' return forecasts closely co-move with expected company earnings, whereas academic experts' forecasts are most closely related to the expected exposure to systematic risk, in line with standard risk-based asset pricing theories.

4.3 An experiment with households: Ruling out risk-based reasoning and beliefs in temporary mispricing

Our third approach zooms in on the mental models of general population respondents. We design experimental interventions to detect previously unobserved traces of reasoning in line with risk-based asset pricing or temporary mispricing. Arguably, the previous evidence already strongly suggests that neither of the two views plays an important role in households' reasoning. However, one might worry that respondents find it challenging to articulate reasoning in line with risk-based pricing or temporary mispricing or that their predicted co-movement of expected returns with other variables is confounded by measurement error or omitted variables. To address these concerns, our additional interventions explicitly rule out changes in risk exposure or temporary mispricing. If either of these two mechanisms were important for respondents' return forecasts, we should see strong shifts in their forecasts in response to our interventions.

Sample We run the experiment in June 2023 with Prolific in the US. 1,182 respondents complete our survey and our sample is balanced across the three included survey arms (see Appendix Table B.5). Appendix Table B.4 provides summary statistics.

Design Our experiment focuses on the *Nike good news* scenario and includes three arms. The survey instructions can be found in Appendix D.3. In the control group, respondents simply complete a shortened version of our main survey. In the *No changes in risk exposure* arm, respondents complete a modified version of the survey, which contains an additional, saliently placed message on the survey screen on which respondents make their return forecast. The message explicitly rules out changes in volatility and exposure to systematic risk:

[No changes in risk exposure] Please assume that there are no differences in the investment-relevant uncertainty between the two scenarios. In particular, this means

- identical volatility: while deviations from the best forecast for the future return of

Table 3 Ruling out risk-based reasoning and beliefs in mispricing

	Dummy for predictions: Good news ⇒ ...			Reasoning

Ruling out mispricing	0.027 (0.031)	-0.025 (0.026)	-0.002 (0.019)	0.039 (0.032)	-0.007 (0.011)
Constant	0.741*** (0.022)	0.177*** (0.019)	0.082*** (0.014)	0.693*** (0.023)	0.030*** (0.009)
Observations	1,182	1,182	1,182	1,182	1,182
R ²	0.004	0.003	0.001	0.002	0.001

Notes: This table analyzes treatment effects of interventions that rule out risk-based reasoning and beliefs in mispricing. The experiment is based on the *Nike good news* scenario. The outcome is a dummy variable for expecting the stock return over the next 12 months to be higher in the good news than in the neutral scenario (Column 1), to be similar across the two scenarios (Column 2), or to be lower in the good scenario (Column 3), or a dummy variable for expressing reasoning in line with a neglect of equilibrium price adjustments – pooling the codes on changes in earnings and investors’ reactions – (Column 4) or with market efficiency – pooling the codes on information efficiency, changes in uncertainty, and changes in factor exposure – (Column 5) in the open-ended question. The independent variables are dummy variables indicating whether a respondent is part of a specific treatment arm, where the control group is the omitted base category. The underlying sample consists of US general population respondents. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Nike stock are possible, the possible deviations are equally sizable and equally likely in both scenarios,

- identical protection against general developments that are deemed unfavorable by investors: in both scenarios, an investment in Nike stock provides the same degree of protection against general developments that are deemed unfavorable by investors, such as the risk that the economy as a whole performs poorly.

Respondents in the *No temporary mispricing* arm are instead presented with a message that rules out temporary mispricing:

[No temporary mispricing] Please assume that the stock price of Nike has changed over the last four weeks since the announcements. The stock price responded to what the announcements revealed about Nike’s future business prospects. Please assume that the current stock price fully and correctly reflects Nike’s future business prospects in both scenarios.

If predictions of higher returns following stale positive earnings news are driven by perceived changes in risk exposure or beliefs in temporary over- or underreaction of stock prices, we should observe strong shifts in households’ return forecasts in response to these treatments.

Results Table 3, Columns 1–3, regress dummy variables for predicting a higher return in the good news scenario, similar returns in both scenarios, or a lower return in the good news scenario on indicators for the two treatment conditions. Compared to the control group, the *No changes in risk exposure* intervention only marginally reduces the portion of respondents forecasting higher returns from 74% to 70% ($p = 0.200$). The *No temporary mispricing* intervention leads to a small, insignificant increase in the fraction of respondents expecting higher returns ($p = 0.372$). These patterns underscore that households’ inclination to equate future earnings with future stock returns does not result from standard asset-pricing reasoning or beliefs in temporary mispricing. Columns 4 and 5 of Table 3 highlight that the interventions also do not change respondents’ tendency to invoke arguments consistent with market efficiency or the neglect of equilibrium price adjustments when they explain their forecast in the open-ended question, consistent with the muted effects on return forecasts.

Taken together, our second main result can be summarized as follows:

Result 2. *Qualitative text data on reasoning, the co-movement of expectations across variables, and additional experimental interventions show that respondents from the general population, retail investors, financial advisors, and even a fraction of fund managers neglect the offsetting effects of equilibrium price adjustments when forming stock return expectations. By contrast, academic experts’ forecasts are mostly based on a belief in market efficiency.*

5 Drivers of equilibrium neglect

A neglect of equilibrium pricing is prevalent in our samples of households and financial advisors. This section explores where this feature of respondents’ mental models of the stock market comes from. We focus on general population respondents and conduct two additional experiments, investigating the role of inattention to market responses and the possibility that households fundamentally fail to understand equilibrium.

5.1 Inattention to trading reactions and price changes

One potential origin of a neglect of equilibrium pricing is inattention to the fact that, over the four weeks since the news announcement, other traders reacted to the news and started to buy or sell the stock. Alternatively, households could be inattentive to the stock price changes that were triggered by these trading responses. Indeed, inattention to indirect, contingent, and downstream consequences is a common behavioral phenomenon (Bordalo et al., 2022b; Eyster, 2019; Gabaix, 2019; Niederle and Vespa, 2023). To explore these possibilities, we design experimental interventions in which we

draw respondents' attention to the trading responses or price changes that happened over the past four weeks before they predict returns over the next 12 months.

Sample We run the experiment in June 2023 with Prolific in the US and collect 1,183 complete responses. Our sample is balanced across the three included survey arms (Appendix Table B.5). Summary statistics are shown in Appendix Table B.4.

Design Our design is based on the *Nike good news* scenarios. The experimental instructions can be found in Appendix D.4. Participants in the control group complete a shortened version of our standard survey.

Respondents in the *Attention to trading reactions* survey arm respond to an additional question after having seen the two scenarios, just before they make their return forecast. They are asked how other traders reacted to the announcement in the scenarios over the past four weeks. The response options include that the announcement (i) made other traders more eager to buy and less eager to sell Nike stock at the old stock price, (ii) did not change other traders' eagerness to buy or sell the stock, and (iii) made them less eager to buy and more eager to sell. Participants in the *Attention to price reaction* arm respond to the same question and additionally answer a question about how other traders' reactions affected Nike's stock price over the past four weeks (whether it increased, did not affect, or decreased the price). Immediately afterward, respondents in these two arms proceed with their return forecast.

The two interventions are unobtrusive and seamlessly fit into the survey flow. Yet, at the same time, they effectively draw respondents' attention to trading reactions and ensuing price changes and ensure that respondents think about them just before forecasting the return. If inattention is indeed contributing to the observed neglect of equilibrium pricing among households, we would expect these interventions to reduce the proportion of respondents predicting higher stock returns in the good news scenario.

Results 88% of respondents who receive the question on trading reactions predict a higher eagerness to buy among traders at the old stock price. Similarly, 88% of respondents who receive the question on price changes predict that prices have increased in response to other traders' reactions. Hence, participants expect that trading responses and ensuing price changes have occurred over the past four weeks.

However, as shown in Panel A of Table 4, neither intervention significantly alters respondents' tendency to expect higher stock returns over the next 12 months in response to stale good news, nor does it reduce the fraction who reveal a neglect of equilibrium pricing in their open-ended elicitation. Thus, even when respondents are made attentive to the trading and price reactions since the announcement, they continue to equate

higher expected earnings with higher expected returns. Inattention to trading and price reactions therefore does not seem to be the primary driver of households' equilibrium neglect.

5.2 A gap in the mental model: Equilibrium not understood

Knowing that the stock became more popular and its price rose over the past four weeks does not keep households from inferring higher future returns from stale good news. This pattern suggests that households interpret price changes through a model without equilibrium pricing. They anticipate price adjustments, but they do not understand their meaning, namely that prices adjust to offset the higher expected future earnings and that no further surplus return can be expected afterwards. Their mental model has a gap: it does not feature equilibrium pricing. To study this possibility, we conduct an experimental intervention aimed at “fixing” the gap in respondents' mental model. We provide respondents with an explanation for how future expected earnings are incorporated into prices in financial markets before respondents complete our standard survey module.

Sample The experiment consists of two waves and was conducted in June 2023 with Prolific in the US. 947 respondents completed the first survey, out of which 588 completed a follow-up survey conducted one to three days later. Appendix Table B.4 provides summary statistics.¹⁵

Design The design is again based on the *Nike good news* scenarios, and the instructions are provided in Appendix D.5. Before completing our standard module, respondents in the treatment group receive a comprehensive explanation detailing how earnings expectations get incorporated into stock prices. This explanation emphasizes the principle that stocks of companies with lower future earnings must be priced lower to attract investors. It further explains how, if this were not the case, stock prices would adjust due to arbitrage until holding stocks of firms with varying levels of earnings is equally attractive. The explanation concludes that “the expected future success of a company is not a reliable indicator of the future success of an investment in its stock.” Respondents are then asked to summarize this principle in their own words. Control group respondents instead receive an explanation about an unrelated topic of similar length and difficulty (the tides and what determines the tidal range). If inference from stale news originates from a fundamental misunderstanding of the concept of equilibrium,

¹⁵Appendix Table B.6 highlights that the sample is balanced across the two included treatment arms in both waves and that participation in the follow-up study is unrelated to respondent characteristics. Participation in the follow-up also does not differ by treatment status ($p = 0.916$).

Notes: This table analyzes the treatment effects of interventions that draw respondents' attention to other market participants' trading reactions and the ensuing price changes (Panel A) or explain the concept of equilibrium to respondents (Panels B and C) before they make their return forecast. The surveys are based on the *Nike good news* scenario (Panels A and B) or the *Amazon good news* scenario (Panel C). The outcome is a dummy variable for expecting the stock return over the next 12 months to be higher in the good news than in the neutral scenario (Column 1), to be similar across the two scenarios (Column 2), or to be lower in the good news scenario (Column 3), or a dummy variable for expressing reasoning in line with a neglect of equilibrium price adjustments – pooling the codes on changes in earnings and investors' reactions – (Column 4) or with market efficiency – pooling the codes on information efficiency, changes in uncertainty, and changes in factor exposure – (Column 5) in the open-ended question. The independent variables are dummy variables indicating whether a respondent is part of a specific treatment arm, where the respective control group is the omitted base category. Panel C is based on the same intervention as Panel B but estimates treatment effects on forecasts and reasoning as measured among a subset of the original respondents in a follow-up survey conducted a few days after the initial survey. The underlying samples consist of US general population respondents. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

our intervention – aimed at filling this mental gap – should reduce the proportion of respondents predicting higher returns in response to stale good news.

Since the explanation of equilibrium pricing and the scenario forecast are integrated in the same survey, experimenter demand effects are a potential concern. For this reason, we conduct a follow-up survey one to three days later, in which demand effects should be mitigated (de Quidt et al., 2018). In the follow-up survey, we present respondents with a different scenario (the *Amazon good news* case) and ask them for an additional forecast and explanation.

Results Column 1 of Table 4, Panel B, illustrates that the intervention explaining equilibrium substantially reduces the proportion of respondents forecasting higher returns in the *Nike good news* scenario, going from 74% to 54% ($p < 0.001$). This is mirrored by an increase in the fraction of participants forecasting similar returns across the two scenarios, rising from 18% to 38% ($p < 0.001$, Column 2). The fraction predicting lower returns in the good news scenario is unaffected by the intervention (Column 3). Columns 1–3 of Panel C illustrate similar patterns in the follow-up survey: for example, the percentage of respondents expecting higher returns in response to positive news drops significantly from 70% to 52% due to the intervention (Column 1, $p < 0.001$). Columns 4 and 5 of Panel B and Panel C highlight that these forecasts are accompanied by a significant increase in the tendency to invoke market efficiency when explaining the reasoning underlying the return forecast ($p < 0.001$). Conversely, reasoning revealing a neglect of equilibrium pricing is significantly reduced among treated respondents ($p < 0.001$).

Taken together, when households are made familiar with the concept of equilibrium, a substantial fraction start reasoning and forecasting returns in line with market efficiency. This effect also illustrates the complementary nature of attention and mental models. If the model is misspecified and does not attribute an important role to the market response, increasing attention to the market response is futile. Instead, a correction of the mental model is required.

Our third main result is the following:

Result 3. *Drawing attention to trading and price responses over the past month does not significantly influence households' return forecasts, but households' forecasts respond to an intervention that explains the concept of equilibrium. Thus, equilibrium neglect originates from a gap in households' mental models – they fail to understand the concept of equilibrium in financial markets.*

6 Equilibrium neglect and expectation anomalies

The evidence we presented so far suggests that the general population, retail investors, and many financial professionals neglect equilibrium when they think about returns on financial markets. This fundamental gap in investors' mental models matters because it likely shapes their return expectations and investment behavior in the real world. In this section, we use panel data on households' actual stock market expectations to test whether equilibrium neglect is predictive of two well-known "anomalies" in expectation formation.

First, households' return expectations tend to co-move positively with expectations about overall economic growth (Beutel and Weber, 2022; Giglio et al., 2021a) and are highest during economic booms and lowest during recessions (Amromin and Sharpe, 2013). This "pro-cyclicality" is contrary to standard asset pricing logic, which would suggest that expected returns are highest during recessions – when economic agents require the highest compensation for bearing risk. However, a mental model neglecting equilibrium pricing naturally produces pro-cyclical expectations: expected earnings are higher in booms, hence equilibrium neglectors also expect higher future returns.

Second, many agents appear to extrapolate past stock returns (Greenwood and Shleifer, 2014; Vissing-Jorgensen, 2003). A neglect of equilibrium pricing could contribute to this pattern: high past returns often reflect positive news about future earnings, which makes equilibrium neglectors also more optimistic about future stock returns, thereby producing a positive co-movement of expectations about future returns with past realized returns.

Data Our general population survey in Germany was conducted as part of the June 2023 wave of the Bundesbank Online Panel – an established survey on household expectations. Respondents repeatedly participate in the monthly surveys, rotating into and out of the panel following an involved scheme. Our working dataset is an unbalanced monthly panel from January 2021 until January 2024 with a total of 30,463 observations, which belong to the 3,852 households that participated in our survey module in June 2023. In all waves, the survey elicits respondents' expectations about the return of the German stock market and overall economic growth over the next 12 months. These expectations are elicited on a 5-point categorical scale. We take this scale as cardinal and z-score it using the mean and standard deviation in our panel data. The exact wording of the expectation questions is presented in Appendix D.6.

Empirical specification We estimate the following two specifications to test whether pro-cyclicality and return extrapolation are more pronounced among equilibrium ne-

glectors:

$$(1) \quad \mathbb{E}_{i,t} \mathbf{r}_{t,t+12} = \alpha_1 \mathbb{E}_{i,t} \mathbf{g}_{t,t+12} \times \text{Eq. neglect}_i + \alpha_2 \mathbb{E}_{i,t} \mathbf{g}_{t,t+12} + \mu_i + \varepsilon_{i,t}$$

$$(2) \quad \mathbb{E}_{i,t} \mathbf{r}_{t,t+12} = \alpha_1 \mathbf{r}_{t-12,t} \times \text{Eq. neglect}_i + \alpha_2 \mathbf{r}_{t-12,t} + \mu_i + \varepsilon_{i,t} \quad ,$$

where $\mathbb{E}_{i,t} \mathbf{r}_{t,t+12}$ is respondent i 's subjective return expectation for the next 12 months, $\mathbb{E}_{i,t} \mathbf{g}_{t,t+12}$ is respondent i 's expectation about economic growth over the next 12 months, and $\mathbf{r}_{t-12,t}$ is the realized return of the German stock market over the 12 months prior to the survey day (which does not vary across respondents interviewed on a given day). The dummy variable “Eq. neglect $_i$ ” takes value one for participants who infer high future returns from stale good news (or low returns from stale bad news) in our main survey module included in June 2023.¹⁶ μ_i are individual fixed effects, which capture permanent differences in return expectations across investors, and $\varepsilon_{i,t}$ is the error term. Alternative specifications additionally control for survey day t fixed effects. We cluster standard errors at the respondent level. Our main object of interest is α_1 , which captures how respondents who neglect equilibrium pricing differentially adjust their return expectations when they increase their expectations about economic growth or when the past realized return increases.

Results Table 5 displays the results. As shown in Columns 1 and 2, respondents' expectations about stock returns co-move positively with their growth expectations. Importantly, this “pro-cyclicality” is significantly stronger among “equilibrium neglectors” ($p = 0.002$). Controlling for date fixed effects (Column 2), a one standard deviation increase in growth expectations is associated with a 0.21 standard deviations higher return expectation, which increases by 20% when a respondent exhibits equilibrium neglect.

Column 3 shows that respondents have extrapolative return expectations. A 10pp higher return in the past twelve months comes with a 0.13 standard deviation higher return expectation. This tendency is about 17% more pronounced among equilibrium neglectors ($p = 0.007$). The size of the effects of the interaction term is substantial given the likely measurement error in our proxy for equilibrium neglect.

We conclude that equilibrium neglect predicts two well-known and important anomalies in return expectations, suggesting a new micro foundation for these phenomena. In Appendix Table B.14, we demonstrate the robustness of these findings to a different coding of expectations, to focusing on past returns over different horizons, and to using alternative proxies for equilibrium neglect. Our fourth and final main result is the following:

¹⁶We showed in Section 4 that – among households – making news-congruent return forecasts largely reflects equilibrium neglect.

Table 5 Equilibrium neglect predicts pro-cyclical and extrapolative return expectations

	Expected future return (DAX, 12m, std.)			
	Procyclicality		Extrapolation	
	(1)	(2)	(3)	(4)

Observations	30,463	30,463	30,463	30,463
R ²	0.470	0.521	0.460	0.498

Notes: This table analyzes the predictiveness of equilibrium neglect for the tendencies to form pro-cyclical or extrapolative stock market return expectations. The underlying sample is panel data from January 2021 until January 2024 on respondents to our German general population survey, which was included in the June 2023 wave of the Bundesbank Online Panel Households (BOP-HH). Columns 1-2 present estimates of equation 1, regressing respondent i 's subjective stock market return expectation for the next 12 months (5-point categorical scale, standardized) on the respondent's expected growth for the next 12 months (5-point categorical scale, standardized), interacted with a dummy indicating whether the respondent exhibits equilibrium neglect according to their prediction in our survey module (making a news-congruent return prediction). Columns 3-4 present estimates of equation 2, regressing respondent i 's subjective stock market return expectation on the realized %-return of the stock market over the past 12 months (divided by 100 for readability), interacted with the proxy for equilibrium neglect. Each household participates at most once in a given survey month, but the realized return and the date fixed effects are calculated on a daily basis. Standard errors clustered at the respondent level are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Result 4. *Equilibrium neglect predicts households' tendency to form pro-cyclical and extrapolative stock return expectations. Equilibrium neglect could thus contribute to well-known anomalies in economic agents' real-world stock market expectations.*

7 Conclusion

Financial markets are governed by return expectations. In this paper, we combine rich expectation data with qualitative text measures of reasoning and experimental interventions to shed light on the mental models that underlie agents' return forecasts.

We document a widespread tendency among households from the general population, retail investors, and financial professionals to draw inferences from stale earnings-relevant news to a company's prospective stock return – a tendency that is absent among

academic experts. This striking difference in their return forecasts results from differences in agents' understanding of financial markets. Academic experts' reasoning aligns with standard asset pricing logic and a belief in efficient markets. By contrast, households and many financial professionals employ a model that directly associates higher future earnings with higher future returns, neglecting the offsetting effect of endogenous price adjustments. This neglect of equilibrium pricing stems from a lack of familiarity with the concept of equilibrium rather than inattention to trading or price responses.

Our tailored empirical approach – surveys conducted with seven different groups of economic agents, represented by more than 11,000 respondents, combining expectation data with rich qualitative text data, including twelve different scenarios and four additional experiments – highlights that it is possible to obtain detailed insights into the reasoning underlying agents' belief formation, which opens promising avenues for future work.

Our findings – that mental models differ across economic agents and that they drastically deviate from standard economic theories among important groups of households and financial professionals who advise and trade for these households – are likely to have significant implications. In particular, equilibrium neglect provides a new perspective on many previously documented anomalies in return expectations and trading decisions. We show that the neglect of equilibrium pricing predicts households' tendency to form extrapolative and pro-cyclical return expectations. Similarly, it may contribute to agents' tendencies to trade on stale news or to believe that monitoring companies is central to successful stock investment – a belief that could lead to high perceived participation costs and non-participation or to a preference for active investment strategies and overtrading conditional on participation. In markets with limits to arbitrage, many of these patterns will have aggregate implications, underscoring the importance of theoretical analyses that explore the interplay of agents with heterogeneous mental models and different levels of understanding of equilibrium feedback (Adam and Nagel, 2023; Barberis et al., 2015, 2018; Bastianello and Fontanier, 2023; Eyster et al., 2019; Glaeser and Nathanson, 2017).

Appendix

Mental Models of the Stock Market

Peter Andre, Philipp Schirmer, Johannes Wohlfart

Summary of the online appendix

Section A provides additional figures.

Section B provides additional tables.

Section C contains additional details on our empirical approach, including the academic expert survey and the hand-coding of the open-ended responses.

Section D summarizes the experimental instructions.

A Additional figures

Figure A.1 Quantitative return forecasts across samples: 1st- and 2nd-order

Notes: This figure shows the average predicted quantitative differences in the return over the next 12 months between the *Nike good news* and the neutral scenario (Panel A) and between the neutral and the *Nike bad news* scenario (Panel B) in our samples of financial advisors, US retail investors, and respondents from the US general population. Analogously, Panels C and D depict the average beliefs about the quantitative differences in other stock traders' return expectations across scenarios. The academic expert survey, the fund manager survey, and the German household surveys do not include quantitative first- and second-order return expectations due to space constraints. Return predictions are winsorized at ± 30 pp. Error bars indicate 95% confidence intervals.

Figure A.2 Directional return forecasts across horizons

Notes: This figure shows the distributions of directional forecasts about the difference in the expected 12-month stock return when investing now (four weeks after the announcement) or when investing in one, two, three or four years from now between the *Nike good news* / *Nike bad news* and the *Nike neutral* scenario. Forecasts are pooled across the *Nike good news* and the *Nike bad news* survey arms. The samples consist of financial advisors (Panel A), US retail investors (Panel B), German retail investors (Panel C), or respondents from the US general population (Panel D). In the survey with German retail investors, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios. The academic expert survey, the fund manager survey, and the German general population survey do not include forecasts for investments at future points in time due to space constraints.

Figure A.3 Word clouds

(a) Academic experts

(b) Fund managers

(c) Financial advisors

(d) US Retail investors

(e) US General population

Notes: The word clouds display the 30 most commonly used word stems in the qualitative text data for each sample. The word (token) size is proportional to the frequency with which it is mentioned within a sample. The text data are tokenized and stemmed, and we drop punctuation, stop words, and the commonly used words “Nike”, “scenario”, “stock”, and “return”. We focus on the surveys conducted in English for comparability.

Figure A.4 Reasoning underlying return forecasts in other scenarios

Notes: This figure displays the distributions of reasoning underlying respondents' return forecasts as expressed in the open-ended question and categorized using our coding scheme, pooling across the six individual stock scenarios and pooling across the four aggregate scenarios. The underlying sample consists of US general population respondents.

B Additional tables

Table B.1 Overview of data collections

Population	Recruitment*	<i>n</i>	Study content
Main descriptive study			
General population (US)	Dynata, June-July 2023, quota-targeted sampling**	2,434	Full descriptive survey. All prediction cases (six individual stocks, four aggregate cases). About 220 respondents per case, except for the two Nike cases, for which we collected 330 responses each.
Retail investors (US)	Prolific, August 2023	408	Full descriptive survey. Two cases: <i>Nike good news</i> , <i>Nike bad news</i> . Case selected randomly.
General population (Germany)	Bundesbank Online Panel (BOP-HH), June-July 2023	3,852	Streamlined, shorter version of survey (only one prediction horizon, no open-ended question on reasoning, no second-order beliefs). All six individual stock prediction cases. The scenarios are “hypothesized”, that is, we talk about fictional firms with fictional names but keep all other scenario features constant. Case selected randomly with equal chance.
Retail investors (Germany)	Online bank, November-December 2023	299	Full descriptive survey. Two cases: <i>Nike good news</i> , <i>Nike bad news</i> . These scenarios are “hypothesized”, that is, we talk about the fictional firm “SportsApparel” but keep all other scenario features constant. Case selected randomly with equal chance.
Financial advisors (US)	CloudResearch, June 2023	406	Full descriptive survey. Two cases: <i>Nike good news</i> , <i>Nike bad news</i> . Case selected randomly.
Fund managers (Germany)	Two asset management firms, November 2023-March 2024	105***	Streamlined, shorter version of survey (only one prediction horizon, no second-order beliefs). Two cases: <i>Nike good news</i> , <i>Nike bad news</i> . For one of our two partnering asset management firms, these scenarios are “hypothesized”, that is, we talk about the fictional firm “SportsApparel” but keep all other scenario features constant. Case selected randomly with equal chance.
Academic experts (global)	Invited via email, June 2023	116****	Streamlined, shorter version of survey (only one prediction horizon, no second-order beliefs). Two cases: <i>Nike good news</i> , <i>Nike bad news</i> . Case selected randomly with equal chance.

*Depending on the targeted population, we work with different recruitment strategies and survey companies.

**The sampling process targeted a sample that mirrors the general population in terms of gender, age (3 groups), region (4 groups), income (3 groups), and education (2 groups).

*** Of the 105 fund managers who provided an expected return prediction, 96 also provided predictions about uncertainty, exposure to systematic risk, and earnings.

**** Of the 116 academic experts who provided an expected return prediction, 102 also provided predictions about uncertainty, exposure to systematic risk, and earnings.

Table continued on next page.

Table B.1 (continued) Overview of data collections

Population	Recruitment*	<i>n</i>	Study content
Real news robustness study			
General population (US)	Prolific, September 2023	484	Between-subject design with real good news and real bad news for the company <i>Siemens Energy</i> (equal chances). Incentivized, quantitative return prediction. Incentivized investment decision.
Ruling out risk-based reasoning and beliefs in mispricing			
General population (US)	Prolific, June 2023	1,182	Experiment with three conditions. Equal chances of being in the control condition, a condition that rules out risk-based reasoning, and a condition that rules out beliefs in mispricing. Based on <i>Nike good news</i> .
Attention study			
General population (US)	Prolific, June 2023	1,183	Experiment with three conditions. Equal chances of being in the control condition, a condition that draws attention to others' trading reactions, and a condition that additionally draws attention to price changes. Based on <i>Nike good news</i> .
Explaining equilibrium study			
General population (US)	Prolific, June 2023	947	Experiment with two conditions. Two waves. Wave 1: Equal chances of being in the control condition (explanation of the tidal range) and a treatment condition (explanation of equilibrium and price adjustments in financial markets). <i>Nike good news</i> prediction scenario. Wave 2: 588 of the initial 947 participants. <i>Amazon good news</i> prediction scenario.

*Depending on the targeted population, we work with different recruitment strategies and survey companies.

Table B.2 Summary statistics for the general population, retail investor, and financial professional samples

Variable	ACS (2022)	US gen. population	US retail investors	GER gen. population	GER retail investors	Financial advisors
Gender

Median equity trades per quarter		0.5	2		2	
Role						
Advisor						50%
Trader						42%
Analyst						70%
Among advisors						
Mean years of advising experience						10
Median number of clients						22
Among traders						
Mean years of trading experience						9
Median annual trading volume						500,000
Sample size	1,980,550	2,434	408	3,852	299	406

Notes: This table presents summary statistics for the US general population, US retail investors, German general population, German retail investors, and financial professional samples. It compares them to benchmark characteristics for the US adult population based on data from the American Community Survey 2022. For the German general population and the German retail investors, household income and assets are reported in euros, while they are reported in US dollars for all other samples. Reported income is annual gross income before taxes and deductions, except for the German general population, where it is annual net income after taxes. For the German general population, equity holdings include non-equity financial assets (other than bank accounts), such as bonds, which account for a very minor share of financial asset holdings in Germany.

Table B.3 Summary statistics for the expert sample

Variable	Academic experts
Personal characteristics	
Male	96%
Mean (median) years since PhD	18.57 (14)
Mean (median) publications in T5 Econ	1.67 (0)
Mean (median) publications in T3 Finance	4.21 (2)
Mean (median) h-index	20.98 (14)
Mean (median) citations	6,594.49 (1,626)
Location	
US-based	40%
Europe-based	48%
Sample size	116

Notes: This table displays the background characteristics of participants in the expert survey. These data are externally collected (i.e., not self-reported). “Mean (median) publications in T5 Econ” is the average (median) number of publications in five highly cited general-interest economics journals (the American Economic Review, the Quarterly Journal of Economics, the Journal of Political Economy, Econometrica, and the Review of Economic Studies). “Mean (median) publications in T3 Finance” is the average (median) number of publications in three highly cited finance journals (the Journal of Finance, the Journal of Financial Economics, and the Review of Financial Studies). “Mean (median) h-index” and “Mean (median) citations” are, respectively, the average (median) h-index and the average (median) total number of citations taken from respondents’ Google Scholar profiles (as of August 2023).

Table B.4 Summary statistics for the additional experiments

Notes: This table presents balance tests for the first wave of the *Explaining equilibrium* study (Panel A) and the second wave (Panel B) and analyzes attrition from wave 1 to wave 2 (Panel C). It shows regressions of respondent characteristics on dummy variables indicating being in the equilibrium explanation condition (Panels A and B) or indicating whether the respondent participated in the second wave (Panel C). The underlying sample consists of US general population respondents. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Notes: This table regresses respondents' directional return forecasts on a set of respondent characteristics, pooling across the *Nike good news* and the (reversely coded) *Nike bad news* survey arms. The outcomes are dummy variables for expecting the stock return over the next 12 months to be higher (lower) in the good news (bad news) scenario than in the neutral scenario (Columns 1, 3, 5, 7, and 9) or to be similar between the news and the neutral scenario (Columns 2, 4, 6, 8, and 10). The underlying samples are financial advisors (Columns 1 and 2), US retail investors (Columns 3 and 4), German retail investors (Columns 5 and 6), US general population respondents (Columns 7 and 8), and German general population respondents (Columns 9 and 10). In the surveys with German retail investors and the German general population, the scenarios use the fictitious company name "SportsApparel" but are otherwise identical to the "Nike" scenarios. For the German general population and the German retail investors, household income and assets are reported in euros, while they are reported in US dollars for all other samples. Reported income is annual gross income before taxes and deductions, except for the German general population, where it is annual net income after taxes. For the German general population, equity holdings include non-equity financial assets (other than bank accounts), such as bonds, which account for a very minor share of financial asset holdings in Germany. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Table B.8 Quantitative return forecasts and investment decisions in the real news robustness study

	Expected return (in %)	Share invested in stock (in %)
	(1)	(2)
Good news	6.447*** (0.775)	26.723*** (2.810)
Constant	4.246*** (0.607)	40.108*** (2.169)
Observations	484	484
R ²	0.126	0.158

Notes: This table regresses a respondent's return forecast and investment decision on a dummy variable taking value one if the respondent was exposed to real stale good news regarding Siemens Energy's future earnings and value zero if the respondent was exposed to real stale bad news. The outcomes are a respondent's quantitative forecast of the return of the Siemens Energy stock over the next 12 months (Column 1) and the share of a £100 investment allocated to the Siemens Energy stock instead of a savings bond paying a fixed interest rate of 2% (Column 2). As preregistered, return predictions are winsorized at ± 30 pp. The underlying sample consists of US general population respondents. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Notes: This table regresses measures of the reasoning underlying respondents' return forecasts as expressed in the open-ended text question on a set of respondent characteristics, pooling across the *Nike good news* and the *Nike bad news* survey arms. The outcomes are dummy variables for expressing reasoning in line with market efficiency (Columns 1, 3, 5, and 7) – pooling the codes on information efficiency, changes in uncertainty, and changes in factor exposure – or with a neglect of equilibrium price adjustments (Columns 2, 4, 6, and 8) – pooling the codes on changes in earnings and investors' reactions – in the open-ended question. The underlying samples are financial advisors (Columns 1 and 2), US retail investors (Columns 3 and 4), German retail investors (Columns 5 and 6), or US general population respondents (Columns 7 and 8). In the survey with German retail investors, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios. For the German retail investors, household income and assets are reported in euros, while they are reported in US dollars for all other samples. Reported income is annual net income after taxes. The German general population survey does not include an open-ended question on reasoning due to space constraints. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Table B.10 Return forecasts differ by underlying reasoning

Dummy for news-congruent expected returns							
(Good news \Rightarrow higher exp. return or bad news \Rightarrow lower exp. return)							
	Academic experts	Fund managers	Financial advisors	US retail investors	GER retail investors	US general population	US general population
	(1)	(2)	(3)	(4)	(5)	(6)	(7)

Scenario	Nike	Nike	Nike	Nike	Nike	Nike	All individual companies
Observations	111	98	406	408	299	672	1,605
R ²	0.681	0.602	0.146	0.334	0.599	0.263	0.285

Notes: This table regresses respondents' directional return forecasts on the reasoning underlying these forecasts as expressed in the open-ended question, pooling across the *Nike good news* and the *Nike bad news* survey arms (Columns 1–6) or pooling across all firm-specific survey arms (Column 7). The outcome is a dummy variable for expecting the stock return over the next 12 months to be higher (lower) in the good news (bad news) than in the neutral scenario. The independent variables are dummy variables for expressing reasoning in line with market efficiency – pooling the codes on information efficiency, changes in uncertainty, and changes in factor exposure – or with a neglect of equilibrium price adjustments – pooling the codes on changes in earnings and investors' reactions – in the open-ended question. The underlying samples are academic experts (Column 1), financial advisors (Column 2), US and German retail investors (Columns 3 and 4, respectively), and US general population respondents (Columns 5 and 6). 111 of the 116 academic experts and 98 of the 105 fund managers answered the open-ended question. In the surveys with German retail investors, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios. The German general population survey does not include an open-ended question on reasoning due to space constraints. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Table B.11 Differences in reasoning explain differences in forecasts across samples

Observations	1,994	1,994	1,994	1,994	1,994	1,994
R ²	0.091	0.118	0.016	0.390	0.423	0.084

Notes: This table examines whether differences in reasoning as expressed in the open-ended question can account for differences in directional return forecasts between academic experts and other investors, pooling across the *Nike good news* and the *Nike bad news* survey arms. The outcomes are dummy variables for expecting the stock return over the next 12 months to be higher (lower) in the good news (bad news) than in the neutral scenario, to be similar across scenarios, or to be lower (higher) in the good news (bad news) than in the neutral scenario. The independent variables are dummy variables indicating whether a respondent belongs to the financial advisors, US retail investors, German retail investors, or US general population sample (the academic expert sample being the omitted base category), and dummy variables for expressing reasoning in line with market efficiency – pooling the codes on information efficiency, changes in uncertainty, and changes in factor exposure – or with a neglect of equilibrium price adjustments – pooling the codes on changes in earnings and investors’ reactions – in the open-ended question. The underlying sample pools academic experts, financial advisors, US and German retail investors, and US general population respondents. The German general population survey does not include an open-ended question on reasoning due to space constraints. 111 of the 11 academic experts and 98 of the 105 fund managers answered the open-ended question. In the survey with German retail investors, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Table B.12 Differences in structured reasoning across samples

	Dummies: Reasoning according to structured question	
	Efficiency (1)	Equilibrium neglect (2)
Financial advisors	−0.356*** (0.049)	0.201*** (0.035)
US retail investors	−0.481*** (0.048)	0.288*** (0.036)
US general population	−0.413*** (0.046)	0.237*** (0.033)
GER general population	−0.462*** (0.042)	0.184*** (0.027)
Constant	0.770*** (0.042)	0.080*** (0.027)
Observations	2,862	2,862
R ²	0.036	0.014

Notes: This table regresses measures of the reasoning underlying respondents' return forecasts as expressed in the structured question included at the end of the survey on dummy variables indicating the different samples, where the omitted base category is the sample of academic experts, pooling across the *Nike good news* and the *Nike bad news* survey arms. The outcomes are dummy variables for reasoning in line with market efficiency and standard risk-based asset pricing – pooling the response options on information efficiency, changes in uncertainty, and changes in factor exposure – (Column 1) and for reasoning consistent with a neglect of equilibrium price adjustments – the response option indicating changes in earnings – (Column 2). The underlying sample pools academic experts, financial advisors, US retail investors, and US and German general population respondents. The German retail investor survey does not include an open-ended question on reasoning. Of the 116 academic experts, 100 answered the structured question. In the survey with the German general population, the scenarios use the fictitious company name “SportsApparel” but are otherwise identical to the “Nike” scenarios. Robust standard errors are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

R ²	0.211	0.216	0.200	0.243	0.576	0.185	0.219

[†]Data are only available for year 1. [‡]Data are only available for the aggregate scenarios.

Notes: This table regresses respondents' directional return forecasts on their forecasts about other variables. The outcome is a dummy variable for expecting the stock return over the next 12 months to be higher (lower) in the good news (bad news) than in the neutral scenario. Columns 1, 4, and 5 pool the *Nike good news* and the *Nike bad news* survey arms. Columns 2 and 3 focus on the *Nike good news* and the *Nike bad news* arm, respectively. Columns 6 and 7 pool all scenarios for stocks of individual firms and the aggregate stock market, respectively. The independent variables are dummy variables indicating whether a respondent expects earnings, uncertainty of the return, the exposure of the return to circumstances investors deem unfavorable, i.e., to systematic risk, market participants' risk aversion, or interest rates to be higher (lower) in the good news (bad news) than in the neutral scenario, and dummy variables indicating whether the respondent increases (for bad news: decreases) the quantitative second-order return expectation more strongly (by more than 0.5pp) than the quantitative first-order expectation in response to the news ("Others over-reacting") and whether the respondent increases (for bad news: decreases) the quantitative first-order return expectation more strongly (by more than 0.5pp) than the quantitative second-order expectation ("Others under-reacting"). The underlying samples are financial advisors (Panel A), US retail investors (Panel B), and the US general population sample (Panel C). We focus on these samples as we elicit directional return forecasts for five horizons and quantitative first- and second-order return expectations in all of these data collections. Robust standard errors are in parentheses. Standard errors are clustered at the respondent level in Columns 4 and 5. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

Table B.14 Robustness checks on pro-cyclical and extrapolative beliefs

Panel A: Pro-cyclicity				
	Expected future return (DAX, 12 months, standardized)			Exp. future return (DAX, 12 months, >0)
	Main specification (1)	Alternative eq. neglector definition (2)	Two-way clustered (3)	Binarized LHS & RHS (4)
Expected growth × Equilibrium neglector	0.039*** (0.015)	0.038*** (0.014)	0.039** (0.016)	
Expected growth	0.206*** (0.012)	0.211*** (0.010)	0.206*** (0.013)	
Exp. growth at least constant × Equilibrium neglector				0.043*** (0.013)
Exp. growth at least constant				0.110*** (0.010)
Respondent FE	✓	✓	✓	✓
Date FE	✓	✓	✓	✓
Observations	30,463	30,463	30,463	30,463
R ²	0.521	0.521	0.521	0.460

Panel B: Extrapolation					
	Expected future return (DAX, 12 months, standardized)			Exp. future return (DAX, 12 months, >0)	
	Main specification (1)	Past 3-month return (2)	Alternative eq. neglector definition (3)	Two-way clustered (4)	Binarized LHS & RHS (5)
Past return/100 × Equilibrium negl.	0.255*** (0.078)	0.330** (0.161)	0.247*** (0.078)	0.255*** (0.079)	
Past return positive × Equilibrium neglector					0.031*** (0.012)
Respondent FE	✓	✓	✓	✓	✓
Date FE	✓	✓	✓	✓	✓
Observations	30,463	30,463	30,463	30,463	30,463
R ²	0.498	0.497	0.498	0.498	0.449

Notes: This table reports robustness checks on the predictiveness of equilibrium neglect for the tendencies to form “pro-cyclical” or extrapolative stock market return expectations. The underlying sample is panel data from January 2021 until January 2024 on respondents to our German general population survey, which was included in the June 2023 wave of the Bundesbank Online Panel Households (BOP-HH). In Panel A (B), Column 1 corresponds to Column 2 (4) in Table 5 and regresses respondent *i*’s subjective stock market return expectation for the next 12 months (5-point categorical scale, standardized) on the respondent’s standardized expected growth for the next 12 months (%-realized stock market return over the past 12 months), interacted with a dummy indicating whether the respondent exhibits equilibrium neglect according to their prediction in our survey module (making a news-congruent return prediction). In Panel A (B) Column 2 (3) shows robustness to an alternative proxy for equilibrium neglect (making news-congruent predictions for the return *and* for earnings). In Panel B, Column 2 uses the realized return over the past three months. Column 3 (4) in Panel A (B) reports the main specification with standard errors two-way clustered at the respondent and the (daily) date level. Column 4 (5) in Panel A (B) regresses a dummy indicating whether the respondent expects a positive stock market return over the next 12 months on a dummy indicating whether the respondent expects growth to remain at least the same over the next 12 months (whether the realized stock market return over the past 12 months has been positive). Each household participates at most once in a given survey month, but the realized return and the date fixed effects are calculated on a daily basis. Standard errors clustered at the respondent level (unless noted otherwise) are in parentheses. * denotes significance at 10 pct., ** at 5 pct., and *** at 1 pct. level.

C Additional details on the empirical approach

C.1 Academic expert survey

Starting from the EconLit publication database, we manually identified the email addresses of all economists who have published at least one article with the JEL code “G: Financial Economics” in a set of leading finance journals or the “top five” economics journals in the years 2015–2019.

We consider the following journals:

- Journal of Finance
- Journal of Financial Economics
- Review of Financial Studies
- Review of Finance
- Journal of Financial and Quantitative Analysis
- Journal of Financial Intermediation
- American Economic Review
- Review of Economic Studies
- Quarterly Journal of Economics
- Journal of Political Economy
- Econometrica

We sent a link to our study to all of these economists by email. We did not send any reminders. In total, we contacted 2,876 economists. 116 economists responded to our survey, corresponding to a response rate of 4%, which is common for such expert surveys.

C.2 Hand-coding of open-ended responses

Each open-text response is assigned to a unique category depending on which line of reasoning is expressed by the respondent. Table C.1 provides a complete overview of all categories in our coding scheme together with examples. The coding scheme was devised before the main data collection and informed by both pilot interviews with households and leading asset pricing theories. Therefore, it contains standard risk-based asset pricing arguments, arguments related to temporary mispricing, and arguments revealing equilibrium neglect. Responses that cannot clearly be assigned to one category are assigned to a residual category.

Table C.1 Overview of categories of the coding scheme

Category	Explanation	Example
Efficient markets		
Information efficiency	The expected returns are the same because the information has already been priced into the market over the past four weeks since the announcement.	“The announcement was 4 weeks ago so it is enough time to be priced in the market. It mentions that it has received a lot of attention already. [...]” (Academic expert)
Risk	The expected return is higher/lower/similar because the uncertainty of the company’s future earnings is expected to be higher/lower/similar.	“I think it will be higher because of the increased risks. it will allow for more volatility and increase the return that can be gained. although this strategy is risky it could bring in more profit” (Retail investor)
Risk factor exposure	The expected return is higher/lower/similar because the risk factor exposure of the future stock return is expected to be higher/lower/similar.	“Negative news already impounded in price but Nike became riskier and the expected return is higher if you assume that the bad news is correlated is marginal utility growth. [...]” (Academic expert)
Risk aversion	The expected return is higher/lower/similar because market participants’ risk aversion is expected to be higher/lower/similar.	Never assigned.
Risk-free rate	The expected return is higher/lower/similar because the interest rates are expected to be higher/lower/similar.	“If the interest rates are increased, I would figure it would increase the investment of stocks or any savings.” (General population)
Temporary mispricing		
Overreaction	The expected return is higher or lower because investors initially overreact to the news, leading to a higher or lower return for some time until a correction occurs.	“I think there is a good chance that the market overreacted in the 4 weeks since the announcement. Therefore, there will be more upside to the stock in scenario two over the next 12 months.” (Retail investor)
Underreaction	The expected returns are higher/lower because investors initially underreacted to the good/bad news, leading to a higher/lower return for some time until the news is fully incorporated in the price.	“In scenario 2, the surprise cost savings should lead to better bottom line. While the market probably reacted up right away during the previous 4 weeks, the upside is most likely not fully priced in.” (General population)
Equilibrium neglect		
Earnings	The expected return is higher/lower/similar because the company’s future earnings or performance are expected to be higher/lower/similar.	“Simply put, the second scenario would lead to a financial set-back for the company, as they are facing a 20 percent increase in production costs, cutting into the company’s profits. The first scenario is more likely to get a good return for investors.” (Retail investor)
Investors’ reaction	The expected return is higher/lower/similar because investors’ interest in or enthusiasm about the stock is higher/lower/similar.	“Since Nike maintained its supply, chain partnership, investors would feel more confident in Nike and the stock price would rise” (Financial advisors)
Residual category		
Other arguments	Any explanation that does not fit the above categories, including repetitions of the scenario text, confused responses, or responses that are too short or too ambiguous to be classified.	“There will be only modest gains in the first scenario and losses in the second.” (Financial advisors)

Notes: This table provides an overview of the different categories in our coding scheme, an explanation for each category, and example extracts from the open-text responses.

C.3 Research transparency

Preregistration We preregistered our surveys and experiments at the AEA RCT Registry (AEARCTR-0011505). The preregistration includes details on the survey design, survey instructions, sampling process, planned sample size, exclusion criteria, and research questions. The following notes document two exceptions and four technical deviations from the preregistration.

- The German retail investor survey was accidentally not preregistered. However, it follows the same structure as the other descriptive main surveys.
- The analysis in Section 6 (Anomalies in stock return expectations) was not preregistered.
- The pre-registration of the fund manager survey indicated that we collaborate with one asset management company. We received fewer responses than we had hoped for, which is why we supplemented the data collection partnering with another asset management company. For these additional responses, we made slight adjustments to the survey, such as switching from the fictitious company name “SportsApparel” to the company “Nike” (as described in Appendix Table B.1).
- We preregistered to randomize the order of the response options for the directional return forecast over the next 12 months in our main descriptive surveys. This randomization was accidentally not implemented in the final collections. Since we find very similar results for good news (households and many professionals predict higher returns in scenario 2) and bad news scenarios (households and many professionals predict higher returns in scenario 1), we are not concerned that the order in which the scenarios are mentioned in the response options matters.
- During our data collection with financial advisors, we realized that we needed to apply more stringent quality controls. We screen participants with open text responses that appear to refuse to engage with the question at all, for example, by pasting unrelated private text messages. These responses were rejected until a total of 405 valid responses were obtained.
- We cannot exclude respondents with extreme response times in the German general population survey because response duration data are unavailable in the Bundesbank Online Panel.

Ethics approval The study obtained ethics approval from the German Association for Experimental Economic Research (XUzKfPvU).

Data and code availability We will make all our data and code available upon publication. The Bundesbank Online Panel (BOP-HH) data are available upon request at the Bundesbank.

Conflicting interests We declare that we have no conflicting interests.

D Experimental instructions

This appendix contains the key instructions from our surveys and experiments. A complete overview of the survey instructions is available at <https://osf.io/b83gf>.

D.1 Main survey

Two scenarios

Please think about the following two hypothetical scenarios.

Scenario 1: Nike maintains supplier partnership

Four weeks ago, on April 29, 2023, Nike Inc. announced the continuation of its partnership with major polyester supplier Toray Industries Inc., in a move aimed at retaining its current supply chain. The continuation of the partnership is expected to maintain the company's current cost structure. Industry experts were not surprised by the announcement, as continuity in supplier relationships is a common practice in the industry.

Scenario 2: Nike secures cost-saving partnership

Four weeks ago, on April 29, 2023, Nike Inc. announced a new strategic partnership with leading recycled polyester supplier Unifi Inc., aimed at reducing raw material costs by 20%. The deal is expected to have a significant impact on Nike's bottom line, making its products more price-competitive. Industry experts were pleasantly surprised by the news and dubbed it an "unexpected success" for the company. They projected the move to significantly enhance Nike's market position in the sports apparel industry.

In both scenarios, the announcement was made four weeks ago and received a lot of attention from stock market traders.

Quiz

Please select all correct statements in the following list. Do not select any incorrect statements.

The scenarios are about a lawsuit against Nike.

The scenarios are about Nike's supply chain partnerships.

In both scenarios, the announcement was made four weeks ago.

In both scenarios, the announcement was made earlier today.

In both scenarios, the announcement did not receive a lot of attention among stock market traders.

In both scenarios, the announcement received a lot of attention among stock market traders.

In scenario 1, Nike maintains its current supply partnerships. In scenario 2, Nike secures a new supply partnership.

In scenario 1, Nike secures a new supply partnership. In scenario 2, Nike maintains its current supply partnerships.

Your prediction

Review the two scenarios (click to open detailed description)

- ▶ **Scenario 1: Nike maintains supplier partnership**
- ▶ **Scenario 2: Nike secures cost-saving partnership**

The announcements were made four weeks ago and received a lot of attention.

Imagine that you invest \$1,000 in Nike stocks today, **four weeks after the announcement was made in the two scenarios**. Imagine that you sell these stocks in twelve months from now.

What would you expect? In which scenario would the return of this investment in Nike stocks be higher?

	The expected return would be ...		
	higher in scenario 1	similar in both scenarios	higher in scenario 2
Return of investment over the next twelve months Invest \$1,000 in Nike stocks today, <i>four weeks after the announcement</i> . Sell these stocks one year from now.	<input type="radio"/>	<input type="radio"/>	<input type="radio"/>

"Similar in both scenarios" means that the difference in returns is smaller than or equal to 0.5 percentage points.

How confident are you in your above prediction? Please answer on a scale from 1 (Not confident at all) to 6 (Very confident).

Not confident at all 1	2	3	4	5	Very confident 6
---------------------------	---	---	---	---	---------------------

Important

On the next page, you will encounter an open question in which we will ask you to explain the prediction that you made on the previous page.

From our experience, it can take about **2 minutes** to complete this question.

Your responses are very valuable for this research project. Therefore, **please take your time to respond carefully.**

[PAGE BREAK]

Your explanation

Review the two scenarios (*click to open detailed description*)

- ▶ **Scenario 1: Nike maintains supplier partnership**
- ▶ **Scenario 2: Nike secures cost-saving partnership**

The announcements were made four weeks ago and received a lot of attention.

For the following investment ...

You invest \$1,000 in Nike stocks today, **four weeks after the announcement was made in the two scenarios.**

You sell these stocks twelve months from now.

... you responded that you expect that the **return of the investment in Nike stocks would be [repeat response]**

Please explain why you think that would be the case.

Table D.1 Overview of all scenarios

Case	Scenario 1	Scenario 2
Nike, good news: New partnership	Nike maintains supplier partnership Four weeks ago, on [...], Nike Inc. announced the continuation of its partnership with major polyester supplier Toray Industries Inc., in a move aimed at retaining its current supply chain. The continuation of the partnership is expected to maintain the company’s current cost structure. Industry experts were not surprised by the announcement, as continuity in supplier relationships is a common practice in the industry.	Nike secures cost-saving partnership Four weeks ago, on [...], Nike Inc. announced a new strategic partnership with leading recycled polyester supplier Unifi Inc., aimed at reducing raw material costs by 20%. The deal is expected to have a significant impact on Nike’s bottom line, making its products more price-competitive. Industry experts were pleasantly surprised by the news and dubbed it an “unexpected success” for the company. They projected the move to significantly enhance Nike’s market position in the sports apparel industry.
Nike, bad news: Loss of partnership	Nike maintains supplier partnership Four weeks ago, on [...], Nike Inc. announced the continuation of its partnership with major polyester supplier Toray Industries Inc., in a move aimed at retaining its current supply chain. The continuation of the partnership is expected to maintain the company’s current cost structure. Industry experts were not surprised by the announcement, as continuity in supplier relationships is a common practice in the industry.	Nike faces supply chain disruption Four weeks ago, on [...], Nike Inc. announced that it is discontinuing its long-standing partnership with major polyester supplier Toray Industries Inc., in a move that is expected to increase the company’s production costs by 20%. The sudden termination disrupts Nike’s supply chain, leading to higher raw material costs. Industry experts were negatively surprised by the news and dubbed it an “unexpected setback” for Nike. They projected the move to significantly weaken the company’s market position in the sports apparel industry.
Amazon, good news: Expansion in Africa	No changes to Amazon’s international strategy Four weeks ago, on [...], Amazon announced that it would move forward with its current expansion plans in the e-commerce sector. As expected, no new country expansions were announced, and none of the existing expansion plans, such as in Africa and South America, were put on hold. The news came as no surprise to e-commerce experts.	Amazon expands in Africa Four weeks ago, on [...], Amazon announced that it would further increase its expansion efforts in Africa, launching its e-commerce business in Nigeria, Algeria, and Morocco later this year. A spokesperson for the company said that negotiations with authorities in these countries—which are among the largest economies on the continent—were proceeding at a faster than expected pace. E-commerce experts were surprised by the good news, and called it an “unexpected success” for the company.
Amazon, bad news: Withdrawal from South America	No changes to Amazon’s international strategy Four weeks ago, on [...], Amazon announced that it would move forward with its current expansion plans in the e-commerce sector. As expected, no new country expansions were announced, and none of the existing expansion plans, such as in Africa and South America, were put on hold. The news came as no surprise to e-commerce experts.	Amazon withdraws from South America Four weeks ago, on [...], Amazon announced that it would be withdrawing from the South American e-commerce market. A spokesperson of the company said the company would end its operations in Brazil in the summer of 2023 and put any expansion plans to other countries in the region on indefinite hold. This decision has raised concerns about Amazon’s expansion potential. E-commerce experts were surprised by the bad news, and called it a “significant setback” for the company.
Novartis, bad news: Loss of patent	Novartis keeps exclusive right to sell heart drug Four weeks ago, on [...], the Food and Drug Administration (FDA) upheld Novartis’ right to the exclusive sale of the heart failure drug Entresto until at least 2028, banning any competitors from producing cheaper substitutes of the drug. This decision ensures that Novartis can continue to sell its drug without contest from competitors for at least five more years. The news came as no surprise to experts of the pharmaceutical industry, who predicted the company’s profits to remain stable in the next few years.	Novartis to lose exclusive right to sell heart drug Four weeks ago, on [...], the Food and Drug Administration (FDA) rejected Novartis’ right to the exclusive sale of the heart failure drug Entresto. The US regulator will open the market for competing generic drug makers, which plan to sell equivalent drugs at lower prices, starting in September this year. The decision is a significant setback for Novartis as the Entresto drug generated the second-highest revenue among all products sold by the company in the past year. Experts of the pharmaceutical industry were surprised by the bad news, calling it an “unexpected defeat” for the company.

Notes: This table provides an overview of all scenarios of the main general population survey.

Table D.1 (continued) Overview of all scenarios

Case	Scenario 1	Scenario 2
BioNTech, good news: Research breakthrough	BioNTech’s cancer drug still years away, market predictions confirmed Four weeks ago, on [...], BioNTech, a German biotechnology company, announced slow but steady progress in its cancer treatment research. A company spokesperson reported on a recently concluded large-scale trial for its bowel cancer drug. The results were promising but indicated that the program still requires years of development before commercial roll-out. The news came as no surprise to industry experts.	BioNTech reports unexpected breakthrough in cancer research Four weeks ago, on [...], BioNTech unexpectedly announced a breakthrough in its cancer treatment research. Results published by the company after the conclusion of a large-scale trial indicate considerably stronger effects of an mRNA-based drug in treating bowel cancer compared to earlier trials, paving the way for a commercial roll-out of the drug later this year. Industry experts were surprised by the good news, and called it an “unexpected success” for the company.
Aggregate stock market, bad news: Negative oil price shock	Crude oil production remains unchanged Four weeks ago, on [...], oil producing countries in the Middle East announced that they plan to keep their crude oil production unchanged. Moreover, the countries announced that no changes to these plans are expected in the foreseeable future. Thus, the globally available amount of crude oil will remain roughly at the current level for the foreseeable future. The news came as no surprise to economic experts.	Crude oil production sharply reduced Four weeks ago, on [...], oil producing countries in the Middle East unexpectedly announced that they will sharply cut their crude oil production in Fall 2023. As a result, the globally available amount of crude oil will be substantially lower over the next years, putting pressure on crude oil prices and further exacerbating the existing energy crisis. Economic experts were surprised by the bad news, and called it a “worst-case scenario” for economic growth in the US.
Aggregate stock market, good news: Breakthrough in solar energy technology	Development of solar energy technology proceeding as expected Four weeks ago, on [...], it was revealed that the development of a new solar panel technology is progressing according to plan, with no significant delays or setbacks reported. The technology holds the potential to enhance the efficiency and affordability of solar power, but it will still require years of development before commercial roll-out. The news came as no surprise to experts.	Breakthrough in development of solar energy technology Four weeks ago, on [...], it became known that there was a groundbreaking advancement in renewable energy technology, enabling the production of solar power at a substantially lower cost. The innovation is anticipated to drive a rapid and substantial expansion of solar power generation, leading to significant energy cost reductions for businesses and consumers across the United States already by the end of this year. Experts were positively surprised by the announcement. They projected the news to generate “significant tailwind” for the US economy, boosting overall economic growth.
Aggregate stock market, good news: Fiscal policy shock	No new government spending programs ahead Four weeks ago, on [...], the government announced that there would be no new stimulus package aimed at boosting economic growth. Instead, the government plans to focus on other key issues during the current legislative period. Experts were not surprised by the announcement, citing previous statements from government officials.	New government spending program to boost economy announced Four weeks ago, on [...], the government unexpectedly announced a new large-scale stimulus package aimed at boosting economic growth by increasing spending on infrastructure projects and providing aid to struggling US businesses. Experts were positively surprised by the news, predicting that the stimulus package would provide a “significant boost” to the US economy.
Aggregate stock market, bad news: Monetary policy shock	Interests rates remain unchanged Four weeks ago, on [...], the Federal Reserve announced that it would keep interest rates unchanged, in line with market expectations. Experts were not surprised by the decision, which was seen as reflecting the current state of the economy. The move is expected to maintain stability in borrowing costs for businesses and consumers.	Fed increased interest rates unexpectedly Four weeks ago, on [...], the Federal Reserve unexpectedly announced a major increase in interest rates. The move follows a recent shift in the composition of the Fed committee, with newly appointed members holding more hawkish views. The move is expected to slow down economic growth by making borrowing more expensive for consumers and businesses. Experts were negatively surprised by the announcement and anticipate the hike to generate “significant headwinds” for the US economy.

Notes: This table provides an overview of all scenarios of the main general population survey.

D.2 Real news robustness study

Below, we provide the key instructions of the real news robustness study. We show the two news conditions and the elicitation of return expectations and investment decisions. A complete overview of the survey instructions is available at <https://osf.io/b83gf>.

Condition: Good news

Four Months Ago: Siemens Energy Announces 7 Billion Euro Wind Power Deal

About four months ago, Siemens Energy made an announcement that received a lot of attention among stock market traders. Here is a summary of the news story.

Siemens Energy, in partnership with Spain's Dragados Offshore, secured a multi-billion euro contract with TenneT, a prominent German-Dutch grid operator. The deal, worth nearly 7 billion euros, is aimed at enhancing the connectivity of wind farms in the North Sea to mainland Germany. This significant contract promises to increase the availability of renewable energy, as it allows for the transfer of up to 6 gigawatts of offshore wind power to the German electrical grid.

The contract involves three key connectivity projects that will link wind-generated electricity from the North Sea to German cities. Siemens Energy will manufacture the main electrical components, such as switchgear, transformers, and converter technology. The projects are an extension of Siemens Energy's ongoing commitment to renewable energy, as the company recently secured similar large-scale contracts at the end of last year.

Recall: This news story broke around four months ago and received a lot of attention among stock market traders invested in or observing Siemens Energy's stock.

Condition: Bad news

Two Months Ago: Siemens Energy Retracts Forecast Amid Wind Turbine Crisis

About two months ago, Siemens Energy made an announcement that received a lot of attention among stock market traders. Here is a summary of the news story.

Siemens Energy is grappling with a crisis due to complications in its wind turbine business. The company has retracted its annual forecast, warning of additional costs in the billions of euros. During a call with analysts, Siemens Energy CEO Christian Bruch admitted that the setback is more severe than he had anticipated. Technical checks on Siemens Energy's wind turbines have revealed "significantly increased" failure rates, with interim reports suggesting that many turbines will need to be replaced or repaired at a cost exceeding one billion euros.

The challenges extend beyond technical issues; productivity improvements in the wind energy business have also fallen short of expectations. Additionally, Siemens Energy highlighted ongoing difficulties in ramping up manufacturing capacities in the offshore wind sector. As a result, Siemens Energy has retracted its profit forecast for the current fiscal year. Some experts started questioning whether Siemens Energy's wind turbine business is even capable of recovery.

Recall: This news story broke around two months ago and received a lot of attention among stock market traders invested in or observing Siemens Energy's stock.

Return expectations

Your prediction

[Review the news story](#) (click to open detailed description)

► **Four Months Ago: Siemens Energy Announces 7 Billion Euro Wind Power Deal**

Consider the following investment.

Invest \$1,000 in Siemens Energy stock today, **several weeks after the announcement was made.**

Sell these stocks in twelve months from now.

Your task is to indicate which return you would expect for this investment.

Recall that the return of an investment in a stock is the percent change in value that you receive from investing in that stock. It includes both dividend payments and the change in the stock price. For comparison, the DAX—which is the German stock market index that represents the 30 largest companies—had an average annual return of 6% over the last ten years.

You can earn additional money based on your prediction. We will calculate the actual return of the investment in a year from now. If your prediction is at most 0.5 percentage points away from the actual return, we will transfer £2 to your Prolific account in a year from now.

Please predict which return you would expect for the above investment.

I predict a return of ...

%

Investment decision

An investment decision

[Review the news story](#) (click to open detailed description)

► **Four Months Ago: Siemens Energy Announces 7 Billion Euro Wind Power Deal**

In the following, we ask you to make a decision on how you would invest £100 for the coming 12 months.

You have the **chance to earn additional money** with your answer to this question. Upon completion of the study, we will randomly select ten participants who will receive a payout equal to the value of their investment after 12 months. If you are selected, this payout will depend on your investment decision, so please consider carefully. The payout will be made in 12 months (plus processing time) in the form of a Prolific bonus payment.

Two investment options are available:

- **Investing in a stock of the company Siemens Energy.** The return on your investment in Siemens Energy stock will be based on the actual return of this stock over the coming 12 months.
- **Investing in a savings bond that pays 2 percent interest per year for sure.** The return on your investment in the savings bond will be 2 percent for sure.

Please decide. How much of the £100 do you invest in Siemens Energy stock and how much in the savings bond?

(Note: The sum of your investments must amount to £100.)

My investment in the stock of <i>Siemens Energy</i>	£ <input type="text" value="0"/>
My investment in the savings bond	£ <input type="text" value="0"/>
Total	£ <input type="text" value="0"/>

D.3 Ruling out risk-based reasoning and beliefs in temp. mispricing

Below, we provide the key instructions for the modified prediction screens that respondents see in the experiment. A complete overview of the survey instructions is available at <https://osf.io/b83gf>.

Control condition

Standard prediction screen as in main survey.

Condition: No changes in risk exposure

The prediction screen contains the following additional information directly before the forecast.

Important for your prediction

Please assume that there are no differences in the investment-relevant uncertainty between the two scenarios. In particular, this means

- **identical volatility:** while deviations from the best forecast for the future return of Nike stock are possible, the possible deviations are equally sizeable and equally likely in both scenarios,
- **identical protection against general developments that are deemed unfavorable by investors:** in both scenarios, an investment in Nike stock provides the same degree of protection against general developments that are deemed unfavorable by investors, such as the risk that the economy as a whole performs poorly.

[Click here to confirm that you have read this information.](#)

Condition: No temporary mispricing

The prediction screen contains the following additional information directly before the forecast.

Important for your prediction

Please assume that the stock price of Nike has changed over the last four weeks since the announcements. The stock price responded to what the announcements revealed about Nike's future business prospects. Please assume that the current stock price fully and correctly reflects Nike's future business prospects in both scenarios.

[Click here to confirm that you have read this information.](#)

D.4 Attention experiment

Below, we provide the key instructions for the modified prediction screens that respondents see in the experiment. A complete overview of the survey instructions is available at <https://osf.io/b83gf>.

Control condition

Standard prediction screen as in main survey.

Condition: Attention to trading reactions

The prediction screen contains the following additional information directly before the forecast.

Please think about the past four weeks. How did stock market traders react to the announcement in scenario 2?

The announcement made stock market traders **more eager to buy and less eager to sell** Nike stock at the old stock price.

The announcement **did not change** how eager stock market traders were to buy and sell Nike stock at the old stock price.

The announcement made stock market traders **less eager to buy and more eager to sell** Nike stock at the old stock price.

Condition: Attention to price reaction

The prediction screen contains the following additional information directly before the forecast.

Please think about the past four weeks. How did stock market traders react to the announcement in scenario 2?

The announcement made stock market traders **more eager to buy and less eager to sell** Nike stock at the old stock price.

The announcement **did not change** how eager stock market traders were to buy and sell Nike stock at the old stock price.

The announcement made stock market traders **less eager to buy and more eager to sell** Nike stock at the old stock price.

How did this reaction of stock market traders affect the Nike stock price in scenario 2 over the past four weeks?

The Nike stock price **increased** in response to stock market traders' reaction.

The Nike stock price **did not change** in response to stock market traders' reaction.

The Nike stock price **decreased** in response to stock market traders' reaction.

D.5 Explaining equilibrium study

Respondents in the treatment condition receive the explanation below before they proceed to the standard survey module (*Nike good news case*). Respondents in the control condition receive an equivalent explanation of the determinants of the tidal range. One day after the completion of the main experiment, all respondents are invited to participate in a follow-up survey which includes the *Amazon good news case*. A complete overview of the survey instructions is available at <https://osf.io/b83gf>.

An important stock market principle

Companies usually differ in their expected future business prospects. Some companies are expected to generate high earnings, others are expected to generate low earnings.

What do you think? Which type of stocks are the better investment?

- Stocks of companies that are expected to generate HIGH earnings in the future.
- Stocks of companies that are expected to generate LOW earnings in the future.

The answer might surprise you. *It often does not matter.*

Why? On the next pages, we want to explain to you the following important stock market principle.

Stock market principle

Whether a company is expected to generate high or low future earnings often does not matter for the expected future return of an investment in its stock.

In other words, the expected future success of a *company* is not a reliable indicator of the future success of an *investment in its stock*.

expected future success of company

≠ expected future success of investment in company stock

[PAGE BREAK]

Why does the principle hold?

It is actually easy to see why this principle holds. First, let's repeat it once more.

Stock market principle [. . .]

The principle holds because expectations for the future are already reflected in today's stock prices.

The stock of a high-earning company is particularly expensive. In fact, it is often so expensive that, from a stock investment perspective, the high expected future earnings are offset by the high stock price today.

Similarly, the stock of a low-earning company is particularly cheap. In fact, it is often so cheap that, from a stock investment perspective, the low expected future earnings are offset by the low stock price today.

[PAGE BREAK]

Why does the principle hold?

The expected future success of a company is not a reliable indicator of the future success of an investment in its stock. This also becomes clear if we think about what would happen if this principle did not hold.

Suppose that investing in high-earning companies was more lucrative than investing in low-earning companies because of their future expected earnings. This situation is unstable. Why? The answer involves four steps.

- Stock traders obviously love lucrative investments. Hence, they would want to hold more of the lucrative high-earning companies and less of the low-earning companies.
- This would trigger a change in stock prices. The demand for the stock of high-earning companies is so high that their stock prices would rise. The demand for the stock of low-earning companies is so low that their stock prices would fall.
- Investing in high-earning companies just became less lucrative because their stocks are now more expensive. Investing in low-earning companies just became more lucrative because their stocks are now cheaper.
- As long as investments in high-earning companies remain more lucrative, this process will continue. Traders will continue to trade and prices will continue to change until the expected earnings of companies do not matter for stock investments anymore.

Hence, in the end, we would be back in a situation where higher expected future earnings of a company do not come with a higher future expected return of investing into the company stock.

[PAGE BREAK]

Summary

Of course, there are other reasons why some companies might have higher expected stock returns: for example, investments in some companies' stocks are more risky or offer less protection against low economic growth. But importantly, expected future earnings themselves do not matter for stock returns.

Stock market principle [...]

D.6 Additional questions from the BOP-HH survey

We make use of the following additional question on expectations about the development of the stock market and the overall economic growth that is regularly asked in the Bundesbank Online Panel Households (BOP-HH), into which our German general population survey was included:

The next question is about your assessment of the general economic development in Germany over the coming twelve months.

Question: What do you think, how will the following figures develop over the next twelve months? Will they ...

[significantly decrease; slightly decrease; remain about the same; slightly increase; significantly increase]

- economic growth in Germany
- the German Stock Index
